Dr. Carey was the son of a master of a small free-school at the village of Paulerspury, in Northamptonshire, where he was born on the 17th of August, 1761. Even in childhood he was remarkable for his intense love of knowledge and ardour in its pursuit. He was apprenticed to a shoemaker at Hackleton, but becoming early the subject of deep religious impressions, he began to preach about the age of twenty, and, without entirely giving up his business, settled at Moulton, in his native county, as pastor of a small Baptist church, whence, in 1789, he removed to Leicester. It was during his residence in obscurity at Moulton that Carey wrote the work which has been the foundation of his fame, and which has brought him to an important degree, to the formation of the Baptist Missionary Society; but it was not published until some years after it was written, it being found difficult to excite even ministers to interest themselves in the cause of foreign missions. The circumstances attending the organization of the society need not be repeated here, but we may state, as an indication of the difficulties to be overcome by its first agents, especially in consequence of the opposition of the East India East India Company to any efforts for the evangelization of Hindustan, that Carey and his companion, Mr. Thomas, were, before the ship in which they set sail (finally left the coast of England, by a late and unceasing struggle, in consequence of threats held out in an anonymous letter which followed the captain; and were thus compelled to take passage in a Danish ship, which was not under the Company's control. For some months after their arrival at Calcutta the missionaries endured great trials, and they were at length compelled to accept engagements to superintend indigo-factories in the vicinity of Mulla, sparing what time andmoney had been assigned to the promotion of their primary object. In 1715 Carey began the work of Bible translations, and in 1799, in that year he removed to Kidderpore, he bought a press and printing apparatus. A third missionary had been sent out in 1799 to join Carey and his fellow-labourer; and in 1799 four missionaries who included Mr. (afterwards Dr.) Marshall, and Mr. Ward, who had been brought up to the printing business, and to whom Carey had, when leaving England, expressed a hope that he might join the missionary profession of the necessity which might arise for practical knowledge of the art, were sent out. As the East India Company would not allow them to settle as missionaries in their dominions, the mission establishment was, about the time of their arrival, removed from Kidderpore to the Danish settlement of Serampore [Serampore, F. C., p. 252], where for many years the work of translating and printing the Scriptures in several languages, various languages of Hindustan was carried on with surprising energy. It appears from the appendix to Dr. Tenth Memoir respecting the Translation of the Sacred Scriptures into the Oriental languages, by the Serampore Brethren, which was published in London in 1834, that the translation and printing of the New Testament into Bengali was completed in 1801; and that between that date and the month of July, 1822, the whole of the Bible was rendered into this language. It is either the whole or part into at least thirty-nine other Oriental languages or dialects, 212,656 copies of the New Testament and other portions of the Bible were issued during that time from the Mission press, in addition to many printed for the British and Foreign and some other Bible Societies. During the same period a great number of religious tracts and miscellaneous works were also produced, in several different languages, including a Bengali map of India, a grammar and a two dictionaries, a semi-weekly newspaper, and a Youth's Magazine, in Bengali and English; and, in Bengali alone, several large volumes of Government Regulations, a History of God's Work in India, a Treatise on Anatomy, intended as the first volume of an Encyclopædia of the Sciences, a Treatise on Geography, and a translation of the Pilgrim's Progress. The list of works in Bengali, Sanscrit, Chinese, and other languages comprises also many important books.

In these great undertakings Dr. Carey was the chief director, while a very large proportion of the actual literary labour also rests upon him. In addition to the office of professor of Oriental language in the college of Fort William, at Calcutta, from its establishment in 1800, until its virtual abolition by the discontinuance of the English professors about the year 1830, he enjoyed a pension from government. He died at Serampore on the 9th of June, 1834, in his seventy-third year, leaving some autobiographical manuscripts which have been used by his nephew, the Rev. Eustace Bird, in a memoir, which was published in London in 1836, to which is prefixed a biographical sketch by his son Jonathan, incorporated in the memoir referred to, it is observed that in all objects connected with the general good of his adopted country, Dr. Carey took an active part, and that he prepared, under the direction of a noble lady then resident in India, the prospectus of an agricultural society in the East, to which was united an horticultural society, of which he was a member, and in the affairs of which he took a lively interest, till his last illness; and he had the gratification to see that the society became at length the most flourishing and interesting society in the East, in which the first distinction of the country, united, and which still continues to maintain the country, united, and which still continues to maintain. A very favourite study with Dr. Carey, whose share in the publication of Biblical and other books in India was very great, was the study of the Rožburg, F. C., p. 197. 'In the Asiatic Society,' continues his son, he also took an active part; and for many years, up to his death, was one of the members of the committee of papers, and afforded considerable information, and in various ways promoted the general interests of the institution.' At his death, he adds, 'the Bishop of Calcutta, in a speech, passed the highest encomiums on the character and talents of Dr. Carey; and a minute was recorded expressing the loss sustained by the society, and their regret at the removal of one of its most excellent members.'

From Remarks on the Character and Labours of Dr. Carey, as an Oriental Scholar and Translator, by H. W. Wilson, Esq., Boden Professor of Sanscrit in the University of Oxford, which is also appended to the Memoir by Eustace Carey, we select the following sketch of his more important and legitimate labours. 'At the time when Dr. Carey commenced his career of Oriental study, the facilities that have since accumulated were wholly wanting, and the student was destitute of all elementary aid. With the exception of the Serampore works, which were produced by the natives of India as sacred and classical, such as the Arabic and Sanscrit, few of the Indian dialects have ever been reduced to their elements by original writers. The principles of their construction are preserved by the grammar or vocabulary forms no part of such scanty literature as they may happen to possess; accustomed from infancy to
the familiar use of their vernacular inflections and idiom, the natives of India never thought it necessary to lay down rules for the pronunciation of the Bengali tongue; and even in the present day they cannot, without difficulty, be prevailed upon to study systematically the dialects which they daily and hourly speak. Europeans, however, are differently circumstanced. With them the art of speaking the Bengali tongue is a sufficient critical knowledge of a foreign tongue. But when the Oriental languages first became the subjects of investigation, those precepts were yet to be developed, and the early students had, therefore, as they gathered words and phrases, to investigate the principles upon which they were constructed, and to frame, as they proceeded, a grammar for themselves. The talents of Dr. Carey were, he adds, 'eminently adapted to such a task': Mr. Wilson says, 'it was impossible to state that Carey's Sanscrit grammar was the first complete one published, his Telinga grammar the first printed in English, his Karnata and Marattas grammars the first published works developing the structure of those languages, his Marattas dictionary one of the first attempted, and his Punjabi grammar the only authority for the language of the Sikh nation; and although, he remarks, 'he must concede to Halhed the credit of first reducing to rule the construction of the Bengali tongue, yet by his own grammar and dictionary, and other useful rudimental publications, Dr. Carey may claim the merit of having raised it from the condition of a rude and unsettled dialect into the position of a regular speech, possessing something of a literature, and capable, through its intimate relation to the Sanscrit, of becoming a refined and comprehensive vehicle for the diffusion of sound knowledge among the Hindustanis.' Some of the works were referred to were of great extent; the Sanscrit grammar, for example, comprising upwards of 1000 quarto pages, and the Bengali and English Dictionary, published in 1815 and 1825, in three volumes, upwards of 2000 quarto pages, and about 50,000 words. An abridgment of the latter work, prepared by Dr. Marshman under the supervision of Dr. Carey himself, was published in 1827 in one thick octavo volume. One of the early and important productions of the press was 'The Ramayána of Valmiki, in the original Sanscrit, with a Prose Translation, and explanatory Notes,' edited by Drs. Carey and Marshman, of which four quarto volumes were published, in 1806 and subsequent years, under the sanction of the Asiatic Society and the Council of Fort William College, but which, unfortunately, was never completed.

It may, at first sight, excite some surprise that the Serampore missionaries should, in some instances, have issued translations in languages or dialects with which none of them were fully acquainted. In this department, observes Mr. Wilson in explanation, 'Dr. Carey took a leading part, and it was in connection with his duty of superintending the translations that he added to his great proficiency in Sanscrit and Bengali, a knowledge of those dialects whose elements he first investigated.' Possessed in this way, he states, 'of at least four languages, and distinct dialects, and of Sanscrit the whole family, and endowed with a genius for philosophic investigation, Dr. Carey was peculiarly qualified to superintend the translation of the Scriptures into a number of cognate languages,' and that 'he was not an error. In connection with his colleagues, he carried the project to so successful an issue as could be expected from the bounded faculties of man.'

In the above sketch of the labours of Dr. Carey frequent allusion has been made to JOSHUA MARSHMAN, D.D., perhaps the most eminent of his colleagues, but of whose particular share in the great undertakings of the Serampore Brethren, as the band of missionaries among whom he and Carey were the most prominent often styled themselves, it is not necessary to give any account. From a statement in the 'Baptist Magazine' for April, 1858, it would appear that he was born in 1767. As before stated, he embarked for India in 1796. In 1826 he visited England on the subject of the disagreement between the Serampore Brethren and the Baptist Missionary Society, which led to their separation in the following year: his son John having previously visited England in 1823 on the same business. In this disagreement, which arose about 1817, the uncompromising and somewhat impracticable spirit of this otherwise excellent man, appears to have had considerable influence in removing the Serampore missionaries from India; he resided there a few years, and remained there till his death on the 5th of December, 1837, a few days previous to which event arrangements were concluded in London for the re-union of the Serampore Mission with the parent society, and for retaining him in the superintendence. In a sketch of his character at the end of the first volume of Dr. Cox's 'History of the Baptist Missions in India,' Dr. Marshman 'is described as the most melioral, power and diligence, of firmness bordering upon obstinacy, and of much warmth. Dr. Marshman's name is especially known by his controversy with Rammohun Roy (Rám- missionaries, in which he was greatly among his countrymen in India by his spirited attacks upon idolatry, and by the publication of a work entitled 'The Precepts of Jesus, the Guide to Peace,' in which, while exposing the precepts, he expresses the miracles of Christ, Dr. Marshman answered this work by a series of articles in the 'Friend of India,' a periodical issued by the Serampore missionaries, which were subsequently republished in London, in 1826, and by Mr. Wilson in the 'Journal of the Deity and Atonement of Jesus Christ, in reply to Rammohun Roy, of Calcutta.' In 1824 appeared a second London edition of Rammohun Roy's work, illustrated with a portrait of the author, and containing replies to Dr. Marshman.

Of the history of the Serampore Mission itself little more need be said. The leading facts are given under MISSIONS, P. C., to which we may add, that although Serampore had been selected as an asylum from the opposition of the East India Company, the missionaries were not disturbed when shortly after their settlement, the place came into the hands of the British Government; its mission establishment has been removed from Serampore to Calcutta, where a handsome printing-office and other premises have been erected. About 1840 the British and Foreign Bible Society began to publish the Bible, which was at first issued by the Serampore mission, public attention having been drawn to the fact that in those versions the words signifying baptism had been so rendered as to distinctly imply the performance of that rite by immersion; and in consequence of this withdrawal of support a new society was formed, under the name of the 'Bible Translation Society,' to provide for the continued maintenance of the Serampore versions, and, in 1842, the London Missionary Society began to encourage the production and circulation of complete translations of the Holy Scriptures competently authenticated for fidelity, it being always understood that the words relating to the ordinance of baptism should be translated by terms signifying immersion.' The question which led to the establishment of this new society occasioned a great deal of controversy, in the course of which there appeared a 'Letter to the Rev. A. Brandram, M.A., on the meaning of the word βάπτισις, and the manner in which it has been rendered in Versions sanctioned by the Bible Society,' by the Rev. F. Henderson, D.D., of Highbury College, in which the whole question of the translation of this word is admirably and learnedly illustrated. This pamphlet was reprinted verbatim in the 'Evangelical Magazine' for June, 1840. From the sixth annual report of the Bible Translation Society, presented to the annual meeting of that body in 1842, it appears that 11,000 copies of the whole or parts of the Scriptures had been printed, and 54,000 copies distributed, in the preceding year, in the Oriental versions; and that the total number printed since 1836 was 188,000. Serampore was closed in 1848.

SERAPHINE, a musical instrument of the keyed kind, recently invented, and may be described as a small organ, in which very short, thin, and narrow steel bars, or springs, put into vibratory motion by means of a bellows acted on by the foot, are used instead of pipes. The principle on which this instrument, as well as every variety of it, is constructed, has been explained under the word ACCORDION, P. C. S., and referred to under the term CONCERTINA, P. C. S. Nothing therefore remains to be added, except that the Seraphine is in the form of a cichofoner, about thirty-seven inches high, forty wide, and twenty-two deep. Its compass is five octaves, including all the semitones, and it is played on in the same manner as any other keyed instrument. It combines the advantages of both organ and pianoforte, by affording the means of prolonging the sounds, the strength of these by the more or less pressure of the fingers and the bellows, while further power of augmenting the loudness is obtained by a pedal acting on the swell. The effect of the bellows, however, is small, and even when very strong, a double bellows, or a skilful player are as surprising as various; and its convenient form, moderate price, together with its invaluable property of standing in tune—perhaps we might say of never going out of tune—are such additional recommendations of the Seraphine, that, we are
Sergell, Johann Tobias, an artist for whom may be claimed the high merit of having commenced that reform in modern sculpture in which he was followed by Calympus, Thorwaldsen, Thorvaldsen, and Anselmi. He was born at Stockholm on the 8th, 1740, and was the son of a gold-foace maker and embroiderer. He himself was at first apprenticed to a stonemason, and worked as such at the royal palace at Stockholm, which was then in repair; and it is no wonder that his early training attracted the notice of the sculptor Larchevaque, who was taken by him as a pupil. After assisting him in modelling the two statues of Gustavus Wasa, and Gustavus Adolphus, Sergell was commissioned to go to Rome, where he remained nearly twelve years, and produced many works that excited general admiration among the professors and patrons of art. On quitting Italy he visited Paris, where his & 'Othryades,' a figure of a wounded Greek soldier, half life size (afterwards placed in the Luxembourg) gained him the appointment of the Academy of Fine Arts. From Paris he proceeded to London, whence he was immediately summoned by Gustavus III, who conferred upon him the post of court sculptor. In 1784 he accompanied that monarch in his visit to Rome; and it was by his advice that Gustavus there purchased among many other valuable works of art the celebrated 'Endymion,' for the royal museum at Stockholm.

Catherine II. was afterwards desirous of securing his talents in her service, and Sergell, as the most celebrated of sculptors, but though with as well as distinction availed him at St. Petersburg, Sergell's attachment to his sovereign and his native land, and his indifference to riches, induced him to remain in Sweden with only certain annuities, and a pension of six hundred rix-dollars. The untimely end of Gustavus, whom he regarded rather as his friend than his master and patron, so affected him that he fell into a deep melancholy, and was for a length of time wholly incapable of doing anything in his profession. It was not till a few years before his death that he regained something like his wonted composure of mind, but it was then almost too late for him to think of retrieving the time that had been lost to art. He died at Stockholm, February 26th, 1814, in his 74th year.

Sergell's works are distinguished by vigour of conception, by energy and grace of style, and by perfect freedom from that mannerism and sickly affectation into which sculpture had fallen in the hands of his immediate predecessors and contemporaries. Among his principal statues are the group of Cupid and Venus, Diomede carrying off the Palladium, Othryades, a Faun, Gustavus III., Orestes dictating to the Muse of History the deeds of Gustavus Adolphus, Mars and Venus, a Venus Callipyge, most of which are in the royal museum. One of his finest productions, a composition in alabaster of a man sitting at a table, windows or open doors behind, which has been called jaeger, is the only one in the model, having never been executed in marble; as was the case with a number of other subjects. His busts and portrait medallions were highly esteemed, both for form, and there being no feeling of goldsmithing in the work, the present eminent Swedish sculptor, was a pupil of Sergell's.

Conversations-Lexicon der Gegenwart; Biographie Universelle.

SEUPELITES, a genus of annulo? (foalins from the Silurian strata of Salop, &c. (Murchison.)

SEWAFALCUS, a genus of grases belonging to the tribe Festucinae. It has unequal heraceous many flowered glumes, the lower are from 4 to 6, the upper 2 to 3. The flower is oblong and trilobed. The outer palea with a short seta formed on three nerves from below the tip. The styles lateral below the summit of the fruit. The spikelets narrow, elongated.

S. cerealis has a loose panicule slightly compound, the simple peduncles being about equaling the oblong glabrous spikelets, the flowers at first loose, irregular, afterwards, distinct, about 4. The fruit is long, covered by the bell of the next flower. The flower is large and downy, the leaves hairy with nearly smooth sheaths. It is native of Great Britain.

S. rustica has a close or elongated erect panicule usually simple, the spikelets glabrous ovate and somewhat compressed. The midrib of the glumes and paleas scabrous towards the top, the leaves and sheaths slightly hairy. It is a common species of Europe, from England to Russia. (Bevington, Manual of British Botany.)

SERRICORNES (Insects), the third family of Penta-
The English system. [WAT. P.C.] The personal servitudes of the Roman law do not correspond, except in some few cases, with any thing in the English law, except limited enjoyment.

[UNTEXTURED, F.C.] The subject of the Roman servitudes would require a long exposition to be treated fully. A good outline is contained in a treatise by van der Ponds in the Bodenbear, i. p. 226, &c., 12th ed.; and in Mackelvie, Macbruch, &c., ii. p. 974, 12th ed.

SUPPORTS, a genus of grasses belonging to the tribe Sessiariaceae. It has a spiked panicle, secale spikeslets tiled all round. The glumes are from 2 to 3 times as long as the spikelet.

S. coriaceus has an ovate slightly one-sided spike, the outer palae terminating in 4 teeth, the dorsal rib rough, with a short excorticate point, the leaves abrupt, with a minute rough point. The roots are tufted, the stem from 6 to 12 inches high. The spike about 3 inch long, and of a bluish-purple colour. This is the only British species. It is found chiefly on mountains.

S. quineta is the Festuc quinetae of Humboldt and others. Humboldt tells us that it is very poisonous.

[LINDLEY, Flora Medica; Babington, Manual of British Botany.]

SESSION, COURT OF, is the Principal Tribunal of Civil Jurisdiction in Scotland. As at present constituted it dates back to the year 1552; but it was then reconstructed on the basis of institutions which had existed at a much earlier period. The early records of the Scottish Parliament show that there was some authority, which in some instances was more or less systematic and legislative function, that of body, was often debased to committees. These were termed Dominii Auditories, or Dominii ad Querellas, and received other like titles.

We find these commissions and their functions to have been of a more distinct position in 1503, when a permanent body received the designation of The Daily Council. It is worthy of observation that these incidents in the history of the court establish a connection between the judicial system and the Court of Session, while in early times it is known to have belonged to the courts of the inferior judges. Parliament being the high jury of the nation, it would be an anomaly that a committee of that body should act through the aid of a jury. The number of the court as finally established in 1552 was fifteen, the usual number of a Scottish jury in former times, and still the number of a jury in a criminal prosecution.

There was then a Lord Chancellor of Scotland, whose functions in some degree resembled those of the same official in England. He presided over the Court of Session, and his judicial functions gradually came to be absorbed in those of the union with England. It was deemed necessary to retain a separate chancellor of Scotland, and the great seal to be appended to private documents for that part of the country being committed to a keeper, the court was presided over by the Lord presiding, or present, in the absence of the chancellor. In 1808 the Court of Session was divided into two divisions: the head of the court, the lord president, who is also now lord justice-general or head of the supreme criminal court, presides in the first division, and the lord justice clerk, or deputy head of the criminal court, presides in the second. In 1815, trial by jury in civil cases on the English system was introduced in Scotland. A separate tribunal was established for jury cases, presided over by a Lord Chief Commissioner, but in 1830 the practice of jury trial was united with that of the Court of Session. It is still tried in a limited number of cases, and far from being popular or satisfactory. The Scottish system of pleading is ill adapted to it, and no means have been found of carrying it through with the promptitude and precision which mark the English practice. In this respect benefit has been in enforcing the separation in all pleadings of the facts stated from the law applied to them. In 1830 two separate courts of limited jurisdiction and small practice—the Admiralty and Commission courts—were established in the Court of Session, and the number of judges was at the same time reduced from fifteen to thirteen. By this measure the court was made to assume less the form of a deliberative assembly acting through a small number of judges, and the particular character of the court before it was divided, and more judicial work was thrown upon individuals. By the act of 1830 (2 Geo. IV., and 1 Will. IV., c. 69.), as carried out by a later act (1 & 2 Vict. c. 118), eight of the judges, formed into two courts of four judges each, sit in the two divisions of the Inner House, where each division forms the court of a second instance. The other five judges are called the Lords Ordinary, and each selects, with the consent of the other four, a separate court, with which he sits in the court of further resort is called the "Outer House." The judgment of a lord ordinary on a closed record is final in the outer house, but it may, within a limited time, be carried to the court of the Inner House, where a final judgment is given. The system of pleading has of late years been much abbreviated and systematised, and the judges, added to the reduced number of judges who sit and give their views on each case, has materially abbreviated the procedure, although it is still the practice for the whole court to be assembled and consulted in difficult cases. The Court of Session is the highest Court of Civil Appeal in Scotland, and the Court of Session is the Court of Session of civil right. It gives remedy when other courts whose function it is to regulate the rights and duties of certain sections of the public as members of a particular class—such as courts martial and ecclesiastical—exceed their powers. The proceedings before the Court of Session in relation to the church courts, were the cause of the great secession from the Scottish church in 1843 [Fair Clackum, F.C.]. As every description of civil question between man and man in Scotland can be competently decided before the Court of Session, it is usual in England to speak of it as a court 'both of law and equity'; but this is a distinction proceeding from incipient and artificial causes, and the Court of Session is in no necessary or proper systematic division of the administration of the law. The Court of Session have the authority enjoyed by the equity courts in England, in the appointment of guardians, and in respect of the protection of property, or of persons where discretionary protection or direction are necessary, and there is no person competent in ordinary course of law to act. In 1839 (2 & 3 Wm. IV., c. 46.), the judges of the Court of Session were appointed according to a certain rotation to perform the duty of judges of the court of justice in matters criminal, and in September of that year, a new practice was adopted by the system of rotation in the performance of the duties of courts of which certain of the lords of session had previously been permanently appointed the judges. By an old practice in Scotland each 'Senser of the College of Justice,' as the judges of the Court of Session are officially called, takes the title of lord.

SESSIONS. The criminal jurisdiction of justices in rural and quarter-seasons is now defined by the 5 & 6 Vict. c. 38, which enacts 'that after the passing of this Act neither the justices of the peace acting in and for any county, riding, division, or liberty, nor the recorder of any borough, shall at any time hereafter sit as a court of justice on the trial of any person or persons for any treason, murder, or capital felony, or for any felony, which, when committed by a person not previously convicted of felony, is punishable by transportation any person for any such offences as are punishable under the 18 heads contained in the first section of the act. The second section provides that any judge of the supreme courts at Westminster, acting under a commission of oyer and terminer and gaz delivery for any county, may, by a writ or writs of certiorari or other process directed to the justices of the peace acting in and for such county, or, to the recorder of any court within the same county, commanding the said justices and the recorder severally to certify and return into such court of oyer and terminer, &c. and all indictments and presentments found or taken by such justices or recorder of offences which after the passing of this act they will not have jurisdiction to try, and the several recognizances, examinations, and depositions relative to such indictments and presentments; and, if necessary, by writ or writs of habeas corpus may cause any person in the custody of any gaol or prison, charged with any such offence, to be removed into the custody of the common gaol of the county, that such offenders may be tried under the said commission. The fourth section empowers any court of general or quarter-seas or adjourned quarter-seas courts, within any county in Scotland, to try such crimes as the said justices or recorder may certify, and return into such court of oyer and terminer, &c. and all indictment and presentments found or taken by such justices or recorder of offences which after the passing of this act they will not have jurisdiction to try, and the several recognizances, examinations, and depositions relative to such indictments and presentments; and, if necessary, by writ or writs of habeas corpus may cause any person in the custody of any gaol or prison, charged with any such offence, to be removed into the custody of the common gaol of the county, that such offenders may be tried under the said commission. The fourth section empowers any court of general or quarter-seas or adjourned quarter-seas courts, within any county in Scotland, to try such crimes as the said justices or recorder may certify, and return into such court of oyer and terminer, &c. and all indictment and presentments found or taken by such justices or recorder of offences which after the passing of this act they will not have jurisdiction to try, and the several recognizances, examinations, and depositions relative to such indictments and presentments; and, if necessary, by writ or writs of habeas corpus may cause any person in the custody of any gaol or prison, charged with any such offence, to be removed into the custody of the common gaol of the county, that such offenders may be tried under the said commission.'
history, with specimens of his works, may be gathered from various parts of Scott's edition of the works of Dryden. Settle, born in 1648 at Dunstable, was entered a commoner of Trinity College, Oxford, in 1666, but left the university without a degree, and came to London in 1668, as an adventurer. He first rose to note in 1671, by the success of his tragedy of 'Cambyseus'; and the prolific Rochester, desirous to humble Dryden, eagerly adopted the new dramatist as a brother to Settle, next tragedy, 'The Empress of Morocco,' composed by an unclesorous patron enjoyed the honour (never vouchsafed to Dryden, the laureate) of being first acted at Whitehall by the lords and ladies of the court; on being transferred to the theatre it was acted to full houses into the second month successively, and copies of it were sold for double the usual price; and the author, intoxicated by his undowered success, precipitated to it a vamping produce; animadverting severely on his rival. Dryden, alarmed and jealous, assailed Shadwell and Rowe in writing scurrilous 'Notes and Observations' on the play, the author answered in the same strain. Political differences obliterated the quarrel begun. But poor Settle's fame was short-lived; and Dryden had little cause to fear him when he was so ill-advised as to advocate the cause of his whig patrons, by publishing, in answer to the 'Abasmon and Achitophel,' a poem entitled 'Abasmon Senior, or Achitophel Transposed.' Not a few thought it a僬worthy of punishment; and, under the name of Doeg, Elkanah became the victim of some of those contemptuous verses which Dryden contributed to the second part of 'Abasmon and Achitophel.' Settle retaliated for the slight, but the lightness of his smoothness of versification, his bombast, and his real poverty, both of thought and fancy, may be accepted as no unfair criticism on his works in general.

Drye, though without knowing her or why,
Made all a trembling kind of melody.
Sagged and stretched and thonged through and thin,
Through sense and nonsense, never out nor in;
Free from the several, weak and false, or bad,
And, in one word, heroically mad.

Down to this time Settle had been a trusted servant and pamphleteer of Shaftesbury and the other whig leaders; and in November, 1690, he superintended with much approbation the burning of the press at Bath. Soon afterwards however he suddenly changed his party, recanting his political heresies in a narrative which he published in 1693. By this change he perhaps preserved for the time his place as poet laureate for the city, and writer of verses for pageants and other civic festivities; but with the revolution his prospects were completely blighted. Although he retained his place as city-poet, he was reduced to great poverty. He had literally to suffer the fate satirical poets are so apt to take. In 1693 he went to London, where he shows at Bartholomew fair in Smithfield; and in one of these he actually performed in person the part of the Dragon slaughtered by St. George, a fact which Pope has charitably interpreted as an allusion to his age. In 1720, having heard that with the aid of some friends he was to act in the Charter-house, and died there in 1723. He was the author of sixteen original plays that were printed, and of a good many occasional and political pieces.

SAX. [Tunis, P. C. p. 469.]

SHAGNAN is a country in Asia, situated in the Upper Valley of the river Oxus, where that river has not yet left the mountains, which enclose the upper part of its course. It lies between 37° and 39° N. lat. and between 70° and 72° E. long., its eastern and western boundaries are impassable known; the river Oxus which runs along its southern and western boundary, divides Shaghan from Badakshan. As the head of this river in these parts, where it is called Jang, is several thousand feet above the sea-level, its course is extremely rapid, which renders the access to Shaghan from this side, very difficult, and for the greater part of the year impossible. The country is traversed by numerous elevated ridges, which are covered with snow for the greater part of the year. These ridges are at their eastern end connected with the immense mountain masses which surround the elevated table-land of Pamir, on which the Oxus originates in the lake of Sir-i-kol. It is true, but its snow is so deep that the climate they do not affect the surface of the land. The greater part of the population subsist on the produce of P. C. S. No. 163.
fastening the sheathing; and the heels of the nails employed are made hollow, and filled with melted zinc. This method in itself has been found effectual in a vessel which has been two years at sea, the corrosion or oxidation of the metal being almost entirely prevented, and the ship returning with a bright and clean surface.

The paper coated with tar, and of various other non-metallic substances, have also been used, and perhaps the most important of these is a kind of felt, into the composition of which a considerable quantity of cow-hair enters. As this material itself feels very imperiously, the sheets are passed, in the process of manufacture, through a boiler of pitch or tar, which increases the cohesion of the fabric. This material, which is sometimes used in conjunction with copper shot, is being laid on immediately beneath the has, according to Barlow ('Treatise on Machinery and Manufactures' in the 'Encyclopedia Metropolitana') the important qualities of being a perfect protection against the worm, which is probably incapable of working its way against the stiff bristly hair which is incorporated in the felt, and of being at once impermeable to water, and so extensible as not to be easily broken by the working which takes place among the timbers of a crazy ship, and which would otherwise produce many leaks. A sheathing composed of a coarse fabric of fibrous material, saturated with a solution of caoutchouc, together with pitch and tar, has been recommended as a cheap and effective felt.

Copper sheathing is usually applied in sheets about four feet long and fourteen inches wide, the thickness being such that a square foot weighs from sixteen to thirty-two ounces,—more than twenty to twenty-four cubic inches of copper; and although the mode of application does not vary materially whether the copper be laid upon the bare planking or upon an interposed layer of tarred paper, felt, or thin boarding. The sheets are pierced with holes, not only round the edges, but also at intervals of three or four inches over the whole surface; they are laid so as to overlap each other about an inch, and are secured to the ship with flat-headed copper nails. 'Great regularity characterizes the author of the 'Sheathing a Ship-Yard,' 'Penny Magazine,' No. 593, 'is observed in the arrangement of the sheets, so that a certain symmetry of appearance, as well as durability, is attained.' After two voyages to the East Indies, according to this authority, 'the coppering requires to be renewed; and the old copper is found to have lost three or four ounces of its weight in the square foot, by the action of sea-water, friction, and other causes.' It may be mentioned as an illustration of the perfect arrangements of a first-rate ship-yard, that a vessel is frequently stripped of her old copper, the surface of the planking prepared for a new sheathing, and sent out thoroughly new; and it is understood that what's entered the dry-dock in which the operation is performed.

SHEERS, or SHEARS, a contrivance used for hoisting the masts of a ship into or out of their place, and occasionally for hoisting heavy gourds or for performing similar operations on shore. The sheers used in masting vessels consist of two large poles, masts, or spars, the lower ends of which rest upon thick planks laid along the sides of the vessel; the upper ends are attached by ropes or by cross each other exactly over the hole in the deck through which the mast is to be dropped, they being sustained in this position by ropes radiating from the top to various parts of the vessel. To this apparatus is attached the tackle necessary for lifting the masts out of the water, when they have been floated to the side of the ship, and lowering them gently into their places. This is the apparatus commonly employed in masting merchant-ships; but the like operation is sometimes performed by means of a sheer-hulk, and sometimes by a masting-house. The sheer-hulk, which is commonly used for masting ships of war, is an old man-of-war cut down to the lower deck, and having a mast, a hundred and twenty feet in length, fixed in the hull, and, supported by the mast, four stout spars or sheers which project obliquely from its side. The tops of these sheers reach to such a height and project to such a distance from the side of the hull, that the vessel to be mastied can come beneath them to be fitted with her lower masts. A masting-house is a lofty building erected for the purpose of performing the operation yet more conveniently, by the aid of a crane and a long series of hoisting-heavy ropes or of draw-sheets, this very considerable distance, beneath which ships may be floated. Such a structure, of great elevation, forms a conspicuous feature of the great ship-building establishment on the Thames at Blackwall.
SATENT STATE OF THE LAW. The act above referred to, gener-
ally called the Jurisdiction Act, was passed for the purpose of
abolishing all those remants of the feudal courts of Scot-
land which were hereditary, or in any other shape of the
nature of property; of bringing all judicial offices within the
appointment of the Crown; and of giving the Crown the exclu-
sive authority and control over the administration of justice.

At the present day, however, there still remain in the
Wirtemberg and the larger counties there are two or
more. Both the sheriff and his substitute are lawyers, but
the latter is the local resident judge, the former generally fre-
quently performs the duties of the sheriff, where he hears appeals
from his substitute, and making occasional visits to his
county. By the Jurisdiction Act it was provided that
such sheriffs should reside in his county during four
months in the year. This provision was for
the sheriff's office to continue as practiced at
the bar to remain in Edinburgh, while the greater portion,
who had given up or had not obtained practice, resided at
their husbands, by the operation of a statute already men-
tioned. This circumstance was the object of much animadver-
sion by the friends of law reform, and a wide difference of
opinion was expressed on the matter, some maintaining that the
sheriffs were unequally chosen, serious consideration, while, in the words of the Report above cited, the
former (who is styled Sheriff Depute) in Edinburgh was in
some degree countenanced by high legal authorities, who con-
sidered the influence and prestige of the city, and of its
court, as an important factor in the
session, during the sitting, to be more useful than a literal
adherence to the statutory rule. It has been supposed that
such an attendance tends both towards a higher degree of legal learning among sheriffs and practice,
being promoted by their occasionally consulting each other.

It was very clear, however, that it was disadvantageous to the
public that there should be any of those judges who neither
reside within their counties nor at any time lose sight of what
the others ought to be. The incumbents receive much
higher salaries than the other sheriffs, and have their time
fully occupied. It has been held that, in regard to the other
considerations, the sheriff in Edinburgh is peculiarly
able to have business at the bar, and giving them duties which
only occupy part of their time, and salaries for which they
would not generally agree to give up their profession, it would
be wise to unite several counties together, and employ law-
ners with salaries equal to the full value of their whole time,
to these enlarged districts. These various opinions were very
actively discussed from ten to fifteen years ago, but it is now
prettv clear that it is in the persons of the sheriffs-substitute,
or permanent local judges, that the public look for the benefi-
cial working of the system. In civil questions an appeal
lies (without new pleadings) from the sheriff-substitute to the
sheriff, but where the former is a solicitor, and an
industrious man, the privilege is seldom used. The salaries of the
sheriffs-substitute have lately been raised, according to
a sound policy advocated by many of the most cautious and
economical politicians in the country; they average at present
about 450L. The salaries of the principal sheriffs vary widely,
but the whole amount of their aggregate incomes, as returned
to parliament in 1843 (Parliamentary Papers, 270), when
defaulters in numbers, given 591 to each.

From the state in which the profession of the bar of Scotland has
been for the past ten years, several of its members have been
induced to accept the office of sheriff-substitute as vacancies
have occurred. The number, given 591 to each.

SHIKARPORÉ is a commercial town, in the province
of Sindé, in 28° 39' N. lat., and 69° 30' E. long. The
town is built on the left bank of the river Indus, and
the waters empty into the Hala Mountains, and about 26 miles from the
western bank of the river. Though more than 250 miles from the
sea, it is only 250 feet above the sea-level. The
city is enclosed by a space of 3983 yards in circuit. They are

built of unburnt brick, but have entirely fallen to decay, for want of repair. They have eight gates. The houses are also of unburnt brick, and have more than one floor; those belonging to the soucers or bankers are of a respectable size, and convenient. The streets are narrow, confined, and dirty in the town; but in the great bazaar, which is the centre of all trade and banking transactions, extends 800 yards, running immediately through the centre of the city. It is protected from the excessive heat by mats stretched from the houses on each side, which produces a stagnation of the air. With the exception of one tolerable moshui on the southern side, Shikarpore possesses no building of importance. The suburbs are very extensive, and a great portion of the population are obliged to live outside the city, particularly the Mohammedans and labouring classes.

The population of Shikarpore, in 1840, consisted of about 30,000 individuals, of whom about two-thirds are Hindus, and the remainder Mohammedans, inclusive of Afghan and Patans. The Hindus carry on all the trade, while the cultivation and mechanical arts of almost every denomination are in the hands of the Mohammedans.

The country round the city is low, and admits freely of irrigation from the inundations of the river Indus by means of small nullas, or water-courses, leading from the Sind Canal. This canal was made by the Mogul emperor for the purposes of irrigation and navigation. The Sind, in its present state, is only navigable from the end of April to the beginning of October, as it has been allowed to ebb up at its mouth, and has generally got out of repair. But it is supposed that at times the river may be rendered navigable for months of the year. The soil in the vicinity of the city is alluvial, and produces rich crops of rice and jowar.

A few articles are manufactured at Shikarpore, but not to any extent, except coarse cotton-cloth, silk-cloth, and Sindu sars. There are also several dyeing-houses, in which cloth made in some of the neighbouring places is dyed and prepared for the market; and there are some paper-mills. This town is the centre to considerable trade conducted between the commercial road between Hindustan, Afghanistan, and Persia, running through it, and leads to the Bolan Pass, which, in spite of its formidable aspect, is much safer than the other roads which connect the valley of the Indus with the territories of Persia, and from this safety has been greatly increased since the British have got possession of the province of Sind, and have suppressed the predatory incursions of the Murries and Boskites, two Belooche tribes who inhabit the mountains contiguous to the pass. The Bolan Pass is also accessible all the year round, and a good road leads from it to Kandahar, and thence to Persia. Shikarpore is as it were built up at the opportunity of the place.

European and India goods are brought to Shikarpore by three different routes. From Caleutta they ascend the Ganges, and are taken to Loordiana, whence they go down the Sutlej, and thence up the Indus, passing through Kyprone. Some of them go from Loordiana to Lahore and Multan. These imports consist of raw Bengal silk, ivory, lacquer, spires of all kinds, coarse cotton cloth, raw Chintz, and silk manufactures, muslin, cotton, cotton, muslin, metal, metals, drugs, indigo, opium, saffron, and dyes. The British textiles fabrics which reach Shikarpore by this route are red-dyed cotton cloth, white cotton cloth, partly-coloured cotton cloth, long cloth, glazed chints, printed, bleached and unbleached cottons, red and white cottons, yellow cotton, Juggernaut muslin, black velvet, shooting cloth, and coloured coarse broad cloth.

The second commercial road connects Central Hindustan with Shikarpore. The goods are brought to Palse in Marwar, situated not far from the Arazvalli range, and are taken through Jullunder and Kyprone to Shikarpore. Only a few articles reach this place by this road, especially sugar, opium, spices, and groceries.

The same articles with European goods are sent from Bombay to Shikarpore by way of Kurache, a sea-port of Sindo west of the Indus. From this place they are transported by land to Sehwun and Larkhana, and then reach Shikarpore. The return of Shikarpore to British India consist of the produce of the country, especially rice, plee, hides, and wool, which is brought from Afghanistan are also exported, and dried fruits.

The exports from Shikarpore to Kandahar and Persia (Herat) consist of indigo, beesw, metals, coarse and fine cotton cloths and calicoes, raw cotton, coarse goods; Mule-cloth, manufactured, piece-goods, spices, raw cotton, coarse sugar, gum arabic, manufactured silk from Herat of various kinds, dried fruits (prunes, dried black grapes, walnuts, dried apricots, almonds, and dates) in great quantities, and also baluchis, olive oil, the (a mixture from the sugar-cane of Jellalabad), broken copper and brass vessels, madder, saffron, safflower, gum salop from Herat, manag, a dye prepared from the walnut-tree, dried mint, caraway-seed, and a very fine description of cotton from Herat, used in embroidery, cochineal, and Uqajand and goodebile, two dyes for silk; the last-mentioned affords a green dye.

From Cutch, a country westward of Shikarpore, are imported slums, cotton goods, and tar, and kar (a kind of potash), produced by the incineration of tamarisk and other salt shrubs. From Bebochistan are brought sauraltan, anemone, slum, and copper.

But Shikarpore is best known in the commercial world by its banking transactions. In 1841 there were in that place thirty-five soucers or bankers, who have agents in all large commercial towns in Western Asia, as far as Bokhara and Kirkand in Chinese Turkestan, and even in Astrakhan and Nishevi Novgorod in Russia. Letters of exchange may be got in all these places payable in Shikarpore, Bombay, and Calcutta.

The climate of Shikarpore is sultry, and the heat excessive from the middle of March to the end of August. There are no periodical rains, though storms are generally looked for at the end of June or the middle of July; severe falls of rain occur at times, but are not considerable. The weather is generally dry and clear, and to this circumstance probably it is to be ascribed that the place is not unhealthy, in spite of the low situation of the town, its being surrounded by stagnant pools close to the walls, and a large space of the adjacent country lying for a considerable period completely under water.

Only for a short period from the middle to the end of September, during which the inundations are drying up, ague in a mild form is not uncommon. The town is frequently swept by a fresh wind in September, and last to the middle of March. Frost and ice are not unusual, and vegetation assumes all the appearance of winter in a northern climate. The mornings at Shikarpore are invariably cold.

Shikarpore is a new town. It was built by the Mogul emperor in 1617, and, as during the last century, since the invasion of Nadir Shah (1739) all the neighbouring countries almost without interruption have been in a state of disorder, the town has never had the opportunity of developing all the advantages of its situation; but as it passed three years ago under the dominion of the British, it is hoped that this change will improve the condition of the place.

(Barrow's Journey through Bokhara; Postam's Memorandum on the trade between the towns of Shikarpore and Kandahar; Postam's Memorandum on the City of Shikarpore, in the Journal of the English and Oriental Societies; On the Commerce of Shikarpore and Upper Sind, in the Transactions of the Bombay Geographical Society.)

SH112S. The different designations which are applied to hunting-stars, according to the lay of meteor of matter, and disposition of salts, are mentioned under SHIP-BUILDING. P. C. p. 396.

SHII [ASTRUMINA, P. C. S.] SHOOTING STARS. The phenomena presented by these meteors, with the different hypotheses which have been proposed in order to account for them, have been noticed under AEROLITES, P. C.; it is therefore intended here merely to state the circumstances which have led to an opinion that the appearances are periodical, and the efforts which have been made, by simultaneous observations on them, to determine the differences between the longitudes of places on the Earth.

On the night of the 11th of November, 1799, M. Humboldt and Bonpland, at Cumania, in South America, observed some thousands of shooting stars in the course of a few hours; and on the same night vast numbers were observed in North America and in Europe. On the night of November 12, 1832, the like meteors were seen in great abundance over all the north of Europe; and on November 12th of the following year, as many as 400,000, according to the computations of Arago, were seen in North America. On the night of November 13, 1834, vast numbers were again observed in America; and on the same day of the same month in the years 1835 and 1836. From these circumstances, and parts of the world was remarkably numerous. Professor
Quetelet, at Brussels, observed, that during the years 1838, 1839, and 1840 the shooting stars occurred on the nights of the 6th and 10th of August more abundantly than on any other nights of the year except the 12th or 13th of November; and it has been observed that since then the sight of the 2nd of June, the 15th of June, and the 6th of December are periods at which the phenomena are, in most years, very frequent. The attention of astronomers has, however, been particularly directed to the 10th of August and the 15th of November as the times at which the recurrence of the phenomena is most probable; but it must be admitted that during the four or five last years the shooting stars have not appeared to be more numerous on those nights than on any other night of the year.

With respect to the use of shooting stars as means of finding the differences between the longitudes of terrestrial stations, the idea was first proposed by Dr. Maskelyne, the astronomer royal, in 1798; and it is obvious that, as their appearance or disappearance is instantaneous to persons stationed at two different places, if it can be ascertained that a meteor observed by persons so situated is the same, the method may become one of considerable utility. The first attempt to ascertain a difference of longitudes by such observations was made in the United States of America in 1835; seven simultaneous observations were made at Philadelphia and New York, on the night of the 10th of November in that year; and the mean of the differences between the times of observation at the two places gave a result which agreed within 1° 2' (in time) with the distance (less 15' longitude) divided by the difference (8h 7m 5s) when determined by other methods. (Silliman's Journal, October, 1840.) On the 10th of August, 1838, twelve simultaneous observations were made at Altona and Breslau, and from the mean by which the value of the difference (8h 7m) in time) between the longitudes of those places, which agrees within one second with the former determinations of that difference. Again, in the same year, the observed times of the first returns of several meteors of different meteors were employed in determining the distance between the meridians of Rome and Naples; and though, on comparing the times of appearance, some discrepancies occurred, yet the times of disappearance agreed simply and directly, and the results gave results agreeing with each other within a few tenths of a second. It is easy to perceive that much uncertainty may exist respecting the precise moment of the first appearance of a meteor, it being scarcely probable that the attention of the observers at different stations should be at the same moment directed exactly to the same point in the heavens.

The impossibility, at present, of anticipating the nights in which the phenomena of shooting stars may be observed, and the small number of observations in which the identity of a meteor is free from uncertainty, are the chief obstacles to the general employment of this method of finding the differences of longitude between terrestrial stations. The number of such meteors do not afford a result on which much dependence can be placed; and a single observation appears to be liable to a risk of error amounting to several seconds of time in comparing different longitudes.

(See Abstracts of the papers, by Messrs. Galloway and Drach, read before the Royal Astronomical Society, in the Monthly Notices for January, 1841, and December, 1841.)

SIDDALIA (in honor of Robert Siddall, formerly Professor of Physics at Edinburgh), a genus of plants belonging to the natural order Rosaceae. It has a concave 10-petalled calyx, the five outer segments accessory. It has 5 yellow or white petals, 5 stamens, and a lateral style. The fruit contains numerous small seeds. S. procumbens has trifoliolate leaves, wedge-shaped leaflets, with three teeth at the apex, rather pilose, the flowers corolline, petals yellow, small, shorter than the calyx. It is found on dry mountains in Scotland, in Europe, Siberia, and North America.

S. peregrina is a native of Cappadocia. It has trifoliolate leaves, the leaflets beset with spiny pili on both surfaces, the flowers corolline, petals yellow, small, shorter than the calyx. It is found on dry mountains in Scotland, in Europe, Siberia, and North America.

(Don, Gardener's Dictionary; Babington, Manual of British Flora.)

SIDDONS. MRS. SARAH, was born at Drexel, in South Wales, July 8, 1753. She was the eldest child of Mr. Roger Kemble and Sarah his wife (whose maiden name was Ward), and, while a mere infant, made her first appearance on the stage on the occasion of her father's benefit. The audience expressed their disapprobation of what they considered too precocious an exhibition; but Mrs. Kemble boldly led the child forward, and with skill united to her beauty, the well-known fable of 'The Boy and the Frog.' From that period Miss Kemble continued to perform regularly in her father's company till she attained her fifteenth year; and, at the early age of thirteen, she sustained the principal female parts in several standard English operas. Having formed an attachment to a young actor named Siddons, which was not agreeable to the family, Miss Kemble was removed from the theatre, and placed under the tuition of the gentleman of Guy's Cliff, Warwickshire, in the capacity of reader and companion. At the age of eighteen the affection of the young couple being unmindful of separation, Mr. and Mrs. Kemble consented to their union. They were married at Trinity Church, Coventry, November 26, 1773, and the young bride returned to the provincial stage at Cheltenham in company with her husband. 'It was a happiness,' remarks Mr. Bosden, in his Life of Mrs. Siddons, 'to see a pair of actors whose mariners to have been born in the exact position of life, and at the precise time she was. Somewhat earlier, her correct feeling might have kept her from the stage, though the true sphere of talent was certainly open to her.' She returned to the management of the theatre when the profession did not disgrace a woman of virtue. Becoming early attached to a man of the most honoured and steady character, the income offered to her beauty did not disturb her peace or impair her talents. She was one of the few smooth and elegant women of the hon. Miss Boyle, Lord Bruce, afterwards created Earl of Aylesbury, and some other noble personages. Upon their strong recommendation, Garrick was induced to send King down to Cheltenham, to witness her performance. In the Fair Pennitent.' The Rev. Henry Bates, afterwards Sir Henry Bate Dudley, was also much struck by her Rosalind; and her transfer to the metropolis being at length determined on, she made her first appearance in 1791, at Drury Lane, on Friday, December 29, 1775, being then only twenty years of age, in the character of Portia, in the 'Merchant of Venice.' Garrick performed Shylock. She was an incomparable lady and an incomparable actress. She received, failed to make any strong impression, being thought more of as a beautiful young woman than as a great or even promising actress. On the revival of 'Richard the Third,' Garrick not having acted Gloucester for five years, he cast Mrs. Siddons the part of Lady Anne. She there, says Mr. Bough, 'met Roscius in all his terrors,' and on the first night hung a little back from timidity. 'I have mentioned,' he continued, 'in another work the glance of reproach that corrected the failure, and the extreme sensibility with which it was long retained.' The fact was, as Mr. Campbell states it, that instead of advancing to the front of the stage to the gaze of the audience, she by 'hanging a little back,' compelled him to act the scene with his back towards the audience, instead of her, an unintentional annoyance which he never forgave her, or at the close of the play, when the remembrances of next campaign were under consideration, his answer to the person who mentioned in her turn 'the young lady,' was simply 'Let her go.' For this latter circumstance we have the authority of a still living contemporary of Garrick and most intimate friend of Mrs. Siddons, whose memory is as clear and retentive as his means of information were numerous and peculiar. But the triumph of Mrs. Siddons, though retarded, was not to be prevented even by so great a theatrical catastrophe as her premature death. In the spring of 1793 Garrick, after a residence at Birmingham, where her genius was acknowledged by the celebrated actor, Henderson, whom he pronounced her to be the first and best of actresses; to have in herself all that her predecessors possessed and all they wanted,' and predicted that 'she would never be surpassed.' From Birmingham she went to Manchester, York, and Bath, increasing her reputation to such a degree that offers were again made to her from the metropolis, and on the 10th of May, 1795, she re-appeared at Drury-lane, as Isabella, in the Fatal Marriage.' On the 30th of October, she performed Euphrasia in 'The Grecian Daughter,' and subsequently enacted Jane Shore. Colissa in the Fair Penitent, and Phoebe in 'Venice Preserved,' a succession of triumphs which established her fame; and at the end of the season she went to Dublin, where her brother John was engaged for three years. In 1789 the celebrated trial of skill took place between the rival
Lady Randolphs, Mrs. Crawford, at Covent Garden, and Mrs. Siddons, at Drury Lane, and added another leaf to the laurels of the latter. In 1784 a cabal was made against her, upon a most unfounded charge of illiberalit...the season she was reduced to devises the scenes and revive the recollections of her former glories; she performed on the 23rd of May for the Covent Garden Theatrical Fund; on the 12th of July for Mr. Charles Kemble's benefit, and the 22nd of the same month at Drury Lane for the fund of that theatre. In November, 1815, she acted for ten nights at Edinburgh for the benefit of the widow and family of her son Horace, who had died at Covent Garden, 80 times in 1815, in charities and charities, and at the request of the Princess Charlotte of Wales, who was, however, unfortunately prevented by illness from witnessing the performance. In 1817 she performed (June 5) for Mrs. Kemble's benefit, and made positively her last appearance upon any stage at Covent Garden, June 9, 1818, for the benefit of Mr. and Mrs. Charles Kemble, in the character of Lady Randolph. For a time after her public father, and in 1812, and Siddons gave occasional readings alternately from Shakespear and Milton at the Argyle Rooms, having been led to do so in the first instance by the kind desire of serving the widow of Mr. Cherry, author of 'The Soldier's Daughter.' She was also honoured by a command to read to Queen Charlotte and the Royal family at Frogmore, and an invitation from the Universities of Oxford and Cambridge. 'Whether this great actress regretted the stated calls to exertion,' says Mr. Bouden, 'I know not.' That she did regret them how there can be little doubt, from the following remarks, which one day made to an old and attached friend, an eminent actor: 'What a life! I am still living from work. I often think it was about the period of the evening when she had been accustomed to repair to the theatre to dress for the performance. 'At this time,' she observed, 'every body in London was talking of me! I was the only person thinking of me!' The tone in which this was spoken, and the sigh which accompanied it, sufficiently indicated the feeling with which she contrasted her public and private life, although still the queen of every circle she surrendered to enter. She died on the 8th of June 1831, about nine in the morning, at her residence in Upper Baker Street, in the 76th year of her age, and the prophecy of Henderson has not yet been falsified. 'The talents of this great woman,' remarks one of her biographers, 'are said to have been slowly developed and the growing claims of her family seemed to be the only unrestrained calls upon her genius. At length fully kindled, it burst forth with a brilliancy that in her own sex has never been witnessed, and rumbled in its charm the spell of the great enchanter Garrick in all but his universality.' Mrs. Siddons lost her second daughter, Maria, in 1793; her husband in 1802; her eldest daughter, Sarah, in 1803; and her son, Henry, in 1815; a third daughter, Cecilia, and her son George survived her. Amongst the most celebrated portraits of this unrivalled actress are a full-length in the character of Isabella holding her hand, which has been engraved; another, in the character of the tragic muse, by Sir Joshua Reynolds, painted in 1784, and now in the collection of the Marquis of Westminster; a third, reading 'Paradise Lost,' by W. H. Holl; and, in 1833, four by Harlowes, who also painted her as Queen Katharine in the well-known picture of the trial scene from 'Henry VIII.' executed for Mr. Thomas Welsh; and shortly before her death she sat to the late H. P. Briggs, Esq., R.A., whose interesting portrait of her (a three-quarter length) was exhibited at Somerset House, but has not been engraved.
alliance between that nobleman and the Earl of Chatham, whom Addington had been in the habit of visiting in his professional capacity. The negotiation, which of course came to nothing, appears to have originated solely with the two physicians—who afterwards quarrelled upon the subject and assassinated each other—a mere mixture of calumny and recriminations—and to have been carried on for the greater part without the knowledge of the two noble persons who were principally concerned. Lord Chatham was at the time on his deathbed.

Meanwhile Addington's son Henry, after having commenced his classical education at Winchester School, had been entered at Brasenose College, Oxford, in January, 1788, and in 1789, and in 1798 obtained the Bachelor's Prize for an English essay. On leaving the university he entered himself a student of Lincoln's Inn, and was called to the bar on the 11th of May, 1784.

Events, however, had by this time taken a course which had the effect of withdrawing him from the further pursuit of the profession upon which he had thus entered. His father's connection with the family of Lord Chatham had led to an intimacy while they were yet boys between him and the younger William Pitt, who was his junior by about three years, but had been in parliament since 1780, and was already, with his father and the macheinon in the administration of the post of first minister of the crown. Addington is said to have been previously fond of attending the debates in the House of Commons; his brother-in-law, James Sutton, Esq., of New Park, had sat with him. On Mr. Pitt's suggestion he stood for and succeeded in getting himself returned for that borough at the general election which preceded the opening of the new parliament on the 18th of May, 1784.

The long political career upon which he now entered was not marked by many events in which he bore a prominent part, and its general course may be briefly traced. So long as he was only a member of the House of Commons—in which he retained his seat for Devizes until he became a peer—he was, as might be expected, one of Mr. Pitt's steadiest supporters. Accordingly, when the office of Speaker became vacant in May, 1790, by the promotion of Mr. (afterwards Lord) Grenville to be secretary of state, Addington, although so comparatively young a member, was put forward as the ministerial candidate, and was elected by a large majority. He filled the chair, with considerable credit if not with any remarkable distinction, till on the retirement of Pitt, in March, 1801, he was induced to undertake the formation and chiefship of a new ministry, with the offices of chancellor of the exchequer and secretary of war. The government thus succeeded rapidly, and with great success, as the journals of the time have recorded. The principal events which now occurred were his accession to the principal posts of the realm, and the transactions of the year 1802, and views had by this time considerably diverged. Addington had come to be considered as the head or leader of the class of persons specially styled the King's Friends; and it was said that he had been at the express request of his majesty that he now assumed office.

The most memorable event of Mr. Addington's short administration was the Peace of Amiens, which proved still shorter than its author's tenure of power. Soon after the renewal of the war in the beginning of 1803, Pitt, who had hitherto supported his old friend, began to intimate an apprehension that he was scarcely equal to the crisis, and then openly joined Fox and opposed the opposition. The result was that Addington resigned, and Pitt was restored to power in May of the following year.

The displaced minister however made no attempt to form a party against his successor. He would probably indeed have admitted as readily as any one else that Mr. Pitt was the preferable person of the two to be at the head of affairs at such a moment, now that he was willing to accept the post under the condition—namely, the abandonment of the question of Catholic Emancipation—which he had formerly rejected, but which the king, and, it must be added, the great majority of the country and both houses of parliament, regarded as indispensable. The resignation of office by Pitt in May, 1804, was a concession on his part of a great point and a great principle, and a decided victory obtained by George III. and his friend Addington. The new government was from the first supported by Addington's adherents, and had the appearance of having a majority. He took office as president of the council, being at the same time made a peer by the title of Viscount Sidmouth. It is said that he accepted this elevation, which removed him from the House of Commons, with much reluctance.

The writer (probably a near relative) of an extended and elaborate memoir of Lord Sidmouth, in the 'Gentleman's Magazine' for April, 1844, has given a full and clear account of every other event of any importance in his lordship's career, merely informing us, without a word of explanation, that he resigned the presidency of the council in July of the same year in which he accepted that office. The causes are thus stated in the 'Annual Register,' in the relation of the proceedings, so distressing to Pitt, which were this year taken against Lord Melville:—"During the whole of these proceedings the new president of the council, Lord Addington, was not present; nor was the minister, and took an eager and an active part in bringing Lord Melville to the bar of public justice: conduct which must have been considered as a defection from the government of which they formed a part, and, as such, must have been deeply resented by the minister. It was also rumoured that other causes of distaste and disagreement existed between Mr. Pitt and Lord Sidmouth at this period: that the former was jealous of the influence which the latter administered in a certain quarter, which had lately been manifested in the conferring of high ecclesiastical dignities; and that, instead of gaining an useful ally, Mr. Pitt had only exposed himself to the additional annoyance of seeing the cardinal's reports were founded in truth it is not our province to decide; but certain it is that on the 10th day of July the Viscount Sidmouth and the Earl of Buckinghamshire resigned their respective offices.

When Mr. Fox and Lord Grenville succeeded to power in February, 1806, after the death of Pitt, Lord Sidmouth was made lord privy seal; and when the ministry was re-constituted in October, he was replaced in his former post of president of the council, which he held till the breaking up of Lord Grenville's government in March following. After this he remained out of office for about five years. Then, in April, 1812, in the last moment before the formation of Mr. Addington's government, he was appointed president of the council for the third time.

In June of the same year, when Lord Liverpool assumed the premiership after the assassination of Mr. Perceval, Lord Sidmouth became secretary of state for the home department. This office, which for the first time gave him much of a real share in the business of government, he continued to hold for the next ten years. He conducted on several occasions, as, for instance, on that of the great meeting for reform, held at Manchester in August, 1815, exposed him to a good deal of popular outcry and obloquy; but he was never charged with being deficient in decision and fearlessness, and he at length obtained the acquiescence of the ministers in the national defence of the country from the privy council was often seriously endangered. He resigned his office in 1822; but at the earnest request of Lord Liverpool he retained his seat in the cabinet for two years longer. He finally retired from official life in 1824; and continued for some years to attend frequently in the House of Lords, though he seldom spoke. He had at no time, indeed, been accustomed to come forward much in debate. He survived till the 1842, and died at his residence, the White Lodge, in Richmond Park, of which he was deputy ranger. Lord Sidmouth was twice married; first in 1791, to Ursula Mary, daughter of Leonard Haunmond, of Chees, in the county of Surrey, Esq., who died in 1811, after bringing his four sons and four daughters; secondly, in 1823, to the honourable Marianne, widow of Thomas Townshend, of Honington Park, in the county of Warwick, Esq., and only daughter of Lord Stowell, who died before him in 1842.

('Gentleman's Magazine,' for April, 1844.)
ment in the year following, and his successor William V. suspended the college altogether. Johann von Siegen retired to Juliers and afterwards to Kampen in Holland, where he died in 1652.

It is known of the life of Ludwig von Siegen from the time that he left the College of Casel 1626 until 1637, except that he was in France and Holland, and it is probable that he was doing military service in this time. In 1637 after the death of the Landgrave of Hesse, he was appointed page to the young prince William VI., by his mother the regent Amelia Elizabeth of Hanau, and in two years afterwards he received the title of Kammerjunker, and served in that capacity until 1641. It was during these years, between 1637 and 1641, that Siegen discovered his new method of engraving, but he removed in 1641, or in the beginning of 1642, to Amsterdam, without imparting his secret in Germany. On the 19th of August, 1642 he sent a letter from Amster-
dam to the Landgrave, enclosing some proofs of a portrait of his mother Amelia Elizabeth, and the plate of these prints is the first mezzotinto engraving. Siegen speaks of his portrait in the letter referred to as executed in a new and astonishing manner, invented by him; and he further observes, that no engraver will be able to devise the manner in which it was executed. This letter still exists among the archives in the Library of the Count of Casel. 3 lines from "L'Historic de la Gravure et Maniere Noire," (History of Mez-
zo-into Engraving).

This earliest mezzotinto engraving, though as the above letter testifies, it was executed in 1642, was not published until 1648, when it appeared with the date altered to that year, together with a portrait of Elizabeth of Hungary; and the prints drawn off by Siegen himself, not already disposed of, were all on the same date, and a number of all three exist still. The inscription of the original print was as fol-
lowing:

"Amelia Elisabetha, D. G. Hassiae Landgravia, &c.
Comitata Hac vinum ad se primum depictum
novum, jam sculptura modo expressum, dedicat concors.
L. a S. Ao Dom. 1642." It is a bust portrait, 16 French inches high by 12 wide, and is rounded at the top.

After the termination of the Thirty Years War in 1648, Siegen left Holland and entered the military service of the duke of Wolfenbuttel, and he married shortly afterwards the daughter of Michael Call, the bishop of Hildesheim, by whom he had several children. In 1654 he returned to Holland, and visited also Cologne, where he resinned the style of Siegen von Sechtem, from the name of his paternal estate, to part of which he also was become entitled. From Cologne went he to Brussels, and there he became acquainted with Prince Rupert, to whom he communicated his new method of engraving. Prince Rupert, to whom the portrait painter Walleran Vaillant, who assisted him in his attempts, and engraved several plates in the style at Brussels and at Frankfort, in 1656 and 1658; a few good prints were also executed by Prince Rupert himself. The secret is, however, said to have been sold by one of Siegen's sons already in the year 1656, and was known at that time at Mainz. This general publication of his discovery, forced Siegen to sign himself, on one or two of his plates at this period, as the in-
venter of this new method of engraving.

It was, however, in England that Mezzotinto engraving was first cultivated to any very great extent or with very great success. In 1650, Prince Rupert accompanied Charles II. to England, and explained the whole process of the new art to his friend Evelyn, who was then engaged on his history of engraving; and in this book, which was published in 1662, he describes it as Prince Rupert's, and published a specimen of the style by the prince. Through this work, entitled 'Sculp-
tura, or the history and art of Chalcography, and engraving in copper,' with an ample enumeration of the most renowned masters, which is annexed to the book, was a new method of engraving or mezzo tinto, communicated by his Highness Prince Rupert to the author of this treatise," Prince Rupert was generally considered the inventor of mezzotinto. Evelyn persuade he was the original inventor of the art, yet from a paper which he himself drew up on the subject, to be read before the Royal Society as a

communication from the prince himself, the invention is not claimed by the prince, and this paper is noticed by Evelyn in his history, in preparation: it was written, but was never read before the Royal Society. In his history, Evelyn heads the following passage thus: "The invention, or new manner of engraving, or Mezzotinto, invented and communicated by his Highness Prince Rupert Count Palantine of Hesse, &c.,' In the paper prepared for the Royal Society, the following passage occurs: "This invention, or new manner of en-
graving, was the result of chance, and improved by a German soldier, who, copying some scarpe of barrel of his musquet, and being of an ingenious spirit, refuted upon it, till it produced effects, which indeed show the delicacy therefore much superior to any invention extant of this art, for the imitation of those masterly drawings, and as the Italians call it that morbidize expressed in the best of their designs. I have had the honour to be the first of the English to whom it has been yet communicated, and by a special indulgence of his Highness, who with his own hands was pleased to direct me with permission to publish into the world, but I have esteemed it a thing so curious, that I thought it would be to profane it, before I had first offered it to this illustrious society.'

Sundrari was better informed as to the origin of this art. 'Though it was done for the first time in England, it is attributed to Siegen, under the title of Siegen: he says, 'the inventor of this art was a lieutenant-colonel in the Hessian service, of the name of von Siegen, who discovered it after the peace in 1648.'

Siegen was born in 1616, as the date of his death is not known; he was still living in 1676, when he was commissioned to engrave the portrait of Anna, and he then styled himself Ludwig Siegen von Sechtem. He appears to have wholly given up engraving in the latter years of his life.

Laube gives the following list of Siegen's engravings:—
the portrait already mentioned of the Landgravine of Hesse, marked L. a S. 1642; Eleonora de Gonzague, wife of the Emperor Ferdinand III., sometimes called the Queen of Bohemia, a bust portrait, marked Onthodorth, 1644; a portrait of H. a S. 1645, high, by 16-6 wide, marked L. a Siegen Inventor fecit 1643; Prince William of Nassau, Guilielmus D. G. Princeps ariacus comes Nassauia, &c. also after Onthodorth, marked L. a Siegen Inventor fecit 1644, 1 foot 7 inches 4 lines high, by 1 foot 3 inches wide; broad; and Augusta Maria Caroli M. B. Rex filia Guilielmhi Princ. a. sous, of the same size and date; the Emperor Ferdinand I. III., marked L. a Siegen in Sechtem ex. novoa, se invento modo sculptur Anno Domini 1654, 1 foot 3 inches 7 lines high, 1 foot 1 line wide; St. Bruno,—L. a S. A. 1654, 11 inches high by 6 inches 11 lines wide; and lastly a Holy Family after Anniabal Caratti, also 1654, which is inscribed to Prince Leopold of Austria—Land, a Siegen huiurs-

SIEYES: EMMANUEL JOSEPH, Count, more gene-

rally known as l'Abbe Sieyes, was born at Frejus on the 3rd of May, 1748. Destined from early youth to the ecclesiastical profession, he completed his studies with success at the Uni-

versity of Paris, where his mind became imbued with the phi-

losophical speculations prevalent at that period, and he applied
himself seriously to political economy, and to the investigation
of the various schemes of social reform which were then so fre-
quently suggested. The liberality of his sentiments does not ap-
pear to have impaired his advancement in the Church. By the
patronage of De Lauberee, Bishop of Chartres, he was
appointed to a canony in that Cathedral, and afterwards became Vicar-General and Chancellor of the dio-

ce. He took an active part in several assemblies of the clergy,
and warmly espoused those opinions which were rapidly produ-
ing the Revolution of 1789. When the disordered state of
the public finances compelled the government to summon the
States-General, and the Whig ministry, which was now
was to be convoked? Whether they were to be called upon,

as in the last assembly of 1614, to vote by classes, or, as
justice and the necessities of the time appeared to require, by
individual votes? The latter is the individual vote. It states that Prince Rupert was the original inventor of the art, yet from a paper which he himself drew up on the subject, to be read before the Royal Society as a
him on the highest pinnacle of political popularity. The first was entitled "Essai sur les Privileges: the second and the most remarkable, "Qui est ce que le Tiers Etat?" in which he asserts that the "Tiers Etat" is the nation itself; he then proceeds to show the extent of its influence on the government of France, and he demands for it a political recognition. The title of the third pamphlet was "Moyens d'Exécution des Représentations de France pour- doux intérêt de l'État en considéré des intérêts de la noblesse et de la nation."

On the convocation of the States-General Siewy was elected deputy for Paris. An opportunity for carrying his scheme into effect was afforded by a marked increase in the power of the nobles and clergy to unite with the "tiers état," and to verify their powers in common; by his eloquent exertions he induced the representatives of the people to constitute themselves into an independent body styled the National Assembly (June 18, 1789). He it was likewise who proposed the oath which was taken by all the members at the "Jeu de Paume" (BAILEY, P. C.) to never to separate themselves, but to assemble whenever circumstances required until the perfect establishment of the constitution.

This sudden and vigorous measure, which must have proved the immediate signal of civil war had not the power of the other orders divided; the already paralyzed, was re- homed by Mirebeau (MIREBEAU, P. C.) at the head of the more moderate of the republican party; it was however carried by a very large majority. So great was the popularity of Siewy that, in the National Assembly, he was greeted by the loud and reiterated applause of the members present, who rose up to receive him. On the meeting of the 22nd of June, when the king declared the resolutions of the Assembly to be null and void, he would have proceeded to disperse, Siewy energetically reminded them that they were "still the same body to-day that they had been the day before, and bid them proceed in their deliberations." "They did deliberate," says a writer in the Foreign Quarterly; "the revolution was the result." Siewy was also the framer of the decree which was passed on the 30th of October, by which the ancient provinces were abolished, and France at last divided into departments all governed by the same law. (FRANCH, P. C.)

He continued to take a prominent part in the deliberations of the National Assembly until the publication of those decrees which he considered of too levelling a nature, and which alarmed him as to the ultimate result of the innovations which he had himself been too eager to introduce. Accustomed to command, he was unable to endure contradiction, and, when he found that the measures which he opposed were carried in spite of his influence, he betook himself to a sudden silence from which even the persuasions of his eloquent colleague, Mirebeau, were unable to rouse him. The most important of those measures was a law regulating the fate of the tithe-holders. To this he was favourable; but he considered that they should be purchased by the landed proprietors, and an indemnity for their loss made to the tithe-holders. To this indemnity, however, he was opposed, and a few days afterwards, on the 1st of April, he died of a painful disease.

"To this he was favourable; but he considered that they should be purchased by the landed proprietors, and an indemnity for their loss made to the tithe-holders. To this indemnity, however, he was opposed, and a few days afterwards, on the 1st of April, he died of a painful disease." (M. de la Vallière, P. C.)

He was named member of the new Comité du Salut Public; on the 19th August of the same year he made a proposition to the Convention to establish a constitutional jubilee, which was rejected. During this time he chiefly occupied himself with the direction of the foreign affairs, and successfully carried on several important negotiations with the European states, and went to Holland to conclude a treaty of alliance.

In the same year Siewy was named by the Council of Antients one of the five directors, but he declined the proffered honour, and Carnot was appointed in his stead.

In 1792 he had a narrow escape from the hand of an assassin, l'Abbé Poule, who, entering his room, fired a pistol at him at arm's length, and one of the balls shattered his hand. He behaved on this critical occasion with his usual coolness, and quietly wrote to his friend, M. de la Vallière, that Poule should return, inform him that I am not at home.

In 1798 Siewy was sent on a mission from the French Government to the court of Berlin, in which, though he failed in his attempt to prevent the declaration of war, he succeeded in securing its neutrality. On his return to Paris the following year he was named member of the Directory, a nomination which showed the disposal of the counsels, as he had openly expressed his dissatisfaction with the directorial government. Placing himself at the head of a conspire which had been formed against three of his colleagues, who were known for their republican sentiments, he pro- cured their forced resignation, and a new Directory was formed in which the majority was favourable to his views. Another important measure which he effected through the instrumentality of the Minister of Police, Fouche, was the closing of the Jacobin Club, a body whose name was associated with all the excesses of the Revolution. These measures, as they destroyed the popularity of the author of the Tiers Etat, and exposed him to the enmity of the populace, made him anxious to secure the support of some military leaders, whose talent and energy to take upon himself the sole direction of the affairs of state. We must have no more dealings with declaimers, he said, among them the Military chiefs there were many at that period, some of them of the highest renown, but they appeared to Siewy to fail in the necessary requisites for a civil ruler. Joubert, in whom he had placed great confidence, was killed, and the new minister was merely a brave and skilful soldier, and Anguerru and Bernad- dotte were too well known for their democratic sentiments. The arrival of Bonaparte from Egypt (BONAPARTE, P. C.; KLEBER, P. C.) determined the difficulty; the penetration..."
of Sieyes discovered in him a fit associate for his designs. They were favoured by the enthusiastic reception which Bonaparte met with from all ranks and parties on his arrival, by the views of this military chief himself, and by the active cooperation of many of the French generals and the most influential members of the legislature. The talents and influence of Sieyes were appreciated by Bonaparte, while the speculative nature of his mind was not without its influence on the latter's forming an object of jealousy. Mutual esteem indeed there was none; they were in the frequent habit of expressing their divergent views in unmeasured terms; but to effect his end the soldier felt the power of the philosopher, in conjunction with the statesman, and the statesman perceived that a salutary change could not take place without the strong support of the soldier.

The Revolution of the 18th Brumaire (9th Nov., 1799) was the result of this co-operation, and Napoleon, Sieyes, and Roger Ducos were the first consuls named, and two commissions of twenty-five members each were appointed from each Council of State to assist the consuls in the formation of a new constitution. In the formation of this constitution, however, Sieyes and Bonaparte soon disagreed; Sieyes was allowed to form a legislature according to his political speculations, and he made it consist of a Senate without the power of debate, and a Tribunate which was to discuss with the Council of State the legislative measures proposed. But to this he was opposed by Bonaparte, respecting the Tribunate, which was to be vested in a Grand Elector, whose sole power was to consist in the nomination of two consuls who were to exercise all the powers of government, Bonaparte offered a vigorous and active resistance.

Discontented with the overbearing character of his political theory, and discovering with characteristic penetration that he had found his master, he refused to act a subordinate part in the new constitution, which was proclaimed on the 5th December, 1799. At this period he may be said to have terminated his public career. His services however were richly rewarded with 600,000 francs and the estate of Croze, which was afterwards exchanged for a magnificent hotel in Paris, and the valuable land on the island of St. Nazaire in the park of Versailles. 'Thus the democratic fervour of the author of the pamphlet 'What is the Tiers Etat?' sunk into the interested apathy of the proprietor of fifty thousand pounds.' (Allion.) This writer quotes also from the 'Memoirs of Gohier' an incident characteristic of the extreme capriciousness of Sieyes, to use no severer term (History of Europe, vol. iii, p. 855), but it must be remembered that Gohier was the President of the Directory on the 18th Brumaire, that he was strongly opposed to Sieyes in political opinions, and that he evinced throughout his Memoirs much personal hostility towards him.

Shorn of his consulate and the empire, Sieyes studiously avoided all participation in power. He declined the offer of the presidency of the Senate, and contented himself with accepting the title of Count. Napoleon borrowed largely from his works; and it is said that he had the talent of finding in many of his political ideas the basis of the legislative measures which he introduced. At the Restoration he was exiled, and only returned to France after the Revolution of 1830, fifteen years afterwards. He died at Paris, in tranquil obsequies, on the 20th June, 1836.

The character of Sieyes has been graphically depicted by Dumont [Douxson, F. C.] in his valuable and interesting Memoirs. 'His manner,' he says, 'was neither frank nor engaging; he was a man with whom it was difficult to become intimate, and who was wont to express his opinion without desiring to enter into any discussion upon it. His writings gave him a well established reputation; he was looked upon as the oracle of the Tiers Etat, and the most formidable enemy of privileges. He was easily excited to a display of ill temper, and inclined to hold the existing state of society (1790). I imagined that this friend of liberty had necessarily a liking for the English nation, and the subject being familiar to me, I introduced it to him, but I was not prepared for the surprise that the English constitution was in his eyes a mere piece of charlatantry to impose upon the people: he seemed to pity my ignorance as I described the various modifications that system had undergone, the branches of the legislature, the changes in the executive, the intrigues of the Romanov family, and the support of Louis XVI. He compared this with the opposition a mere court trick ('manège d'antichambre').

The only thing he approved of among the English was trial by jury, which, however, he but little understood, and, in common with most Frenchmen, he had formed wrong notions respecting it. In a word, it was his opinion that the English but as children in the art of framing a constitution, and that he considered himself capable of giving a much better constitution to France.' (Dumont, Souvenirs de Mirabeau, p. 69, 68, Paris, 1842.)

The writings of Sieyes, not already mentioned, are:

SIGNEOGLI, Luca, a celebrated Italian painter, born at Cornosa in 1439, was the son of Egidio di Ventura SIGNORELLI the younger and Vasaari; he was the pupil of Piero della Francesca, with whom he worked at Arezzo, where he lived with his uncle Lazzaro Vasaari.

Vasari mentions many of Luca's works, few of which however still exist; but the altar-piece of St. Onofrio, painted in 1484, is still in the cathedral of Perugia, and there are two other pictures in the cathedral of Volterra; there are also still some pictures by him at Orvieto, Rome, Cortona, at Siena, and in its neighbourhood, and in the Florentine gallery of the Medici, to which he has been, and is still, a great ornament. His most celebrated work is the fresco of the Last Judgment in a chapel of the church of the Madonna or cathedral at Orvieto. The painting of this chapel of the Madonna di Montecito, of which he commenced in 1494, and finished in 1500, is the fresco of Luca SIGNORELLI, who however painted only part of the ceiling, and it was completed many years afterwards by Luca SIGNORELLI. The contract containing the continuation of these frescoes by SIGNORELLI was made by the Prior of the Church of St. Nicholas in 1499. The completion of the ceiling for 200 ducats, and the walls for 600 ducats, besides free lodging, and two measures of wine and two quarters of bread every month. The ceiling was finished in 1500; when the works were finished, it is not known whether the ceiling was done actually within the first year, and this may from the amount of the remuneration be fairly estimated at about one quarter of the whole, the chapel was probably completed in 1508 at latest. The frescoes comprise the history of Antichrist, the Resurrection of the Dead, Hell, Paradise; and such is the vigour and boldness displayed in these works, especially in the invention and the naked figure, and the foreshortenings, that Vasaari and many others have pointed to SIGNORELLI as the immediate precursor of Michael Angelo. Vasaari says that Michael Angelo always expressed a high opinion of SIGNORELLI, and observes that all may see that he made use of the inventions of Luca in the Last Judgment in the Sistine Chapel, especially in the forms of the angels and demons, and in the arrangement.

Luca SIGNORELLE was elected to the Academy of St. Luke for the prize of Sixitus IV. in the Sistine Chapel, which was won by Cosimo Roselli. [ROSSELLI, P. C. S.] He retired in his old age to Cortona, where his Italian fame was rivalled by the Roman and Florentine. Cosimo Roselli, for whom Vasari as having been a man of very high character, and he adds that he always lived more like a nobleman than an artist: he died in 1561, aged eighty-two. The frescoes of the cathedral are described in part by Vasari in his 'Storia del Duomo d'Orvieto,' Rome, 1791. The
design, though full of power, is hard, and the colouring wants harmony.

(Vaas, "Vite de' Pitteri," ed. Schole.)

The Indus was once a great river (see Dist. Nat. 26, c 8, ed. Hard.) for an umbelliferous plant), a genus of plants belonging to the natural order Umbelliferae, and the tribe Seseliaceae. The calyx is obsolete; the petals ovate, oblong, entire, or slightly toothed; the sepals an indented lobe, sessile, truncaate, or appended at the base.

S. pratensis, Meadow Pepper Saxifrage, has an angular stem, supra-compound leaves, pinnate leaflets with the segments raised, and a blossom like a poppy, and an spreading spinous point. The receptacle is scaly. The fruit compressed, its terminal area surrounded by a papillose ring. S. pratensis, is the only species. It has a stem from 8 to 6 inches high, with leaves of a very large size, lancelate, lacerate, wavy, and clasping the radical leaves, pinnaed, and usually variegated green and white. The involucral scales closely adpressed below. The florets are purple, with a white tube. This plant is found in waste places in Great Britain.

(Babington, "Manual of British Botany.")

SINDES or SCINDA is that part of Hindostan which extends from the sea to the near place where the river is joined by the Chinah, which brings it to the united waters of the five rivers of the Panjab. It lies between 23° 30' and 28° N. lat., and 76° and 71° E. long. It extends in length from south to north more than 600 miles, and its average width may be 200 miles. This gives an area of 72,000 square miles, or about 14,000 square miles more than England inclusive of Wales, and nearly as much less than the whole area of Great Britain.

On the south and south-west it borders on the Indian Ocean, and its eastern districts are separated from the province of Outech by the Rumm. To the east of it, and chiefly within its bounds, are the Indian Desert, the Desert of the Rajapo States of Marwar and Jesulmure. On the north-east are the territories of the Khan of Bhawulapore, south of those of the Panjub or Seila. The north-western corners of Sind and the Bootees hills and the South Waziristan, are the limits of the boundaries on the Rajapo States of Marwar and Jesulmure. On the west of the territory of the Khan of Bhawulapore, and south of those of the Panjub or Seila. The north-western corners of Sind and the Bootees hills and the South Waziristan, are the limits of the boundaries on the River Indus. Only the river Indus is the river of India. The river Indus is a very large river, and its waters spread over a great extent of country. In those areas of the river however which are not watered by the river Indus, the dams have no opening. The whole volume is thus driven back and spreads over the district above the dam, and the bed of the river below it would remain dry if the water was not carried by the canals over the country did not find by these canals a way to the bed of the river below the dam. These dams are called bunda.

The river begins to rise in April. Early in May the waters begin to point out the necessity of deepening and cleaning out the various canals. Towards the middle of June there is sufficient water for sowing the crops, which are sown in the open and are cut out by the third of September. At the end of September the waters are confined to the bed of the river. A few miles below the point where the Indus is joined by the Chinah, the river enters Sind. About 60 miles lower down, and only about 100 miles above the sea, it begins to divide into arms.

At this place (about 28° N. lat.), the river divides into two branches off on the eastern side, which is called the Eastern Narra. It appears that this arm formerly received a great, if not the greatest, part of the waters brought down, but that the river changed its course more to the west. After this event had taken place, a bund was erected across the Narra, near the coast town of Arour, which is still called the Arour Bund. Thus the Narra was deprived of the annual supply of water, except when the river enters the Indus rose to an unusual height, as in 1831. Its bed would generally be dry, if it did not receive a small supply of water from a remarkable depression, which extends from the vicinity of Bhawulpore to that of Arour, which running water is found during four or five months of the year. This depression, being considerably lower than the head of the Narra, receives large quantities of water from the Narra, and also other small streams, in consequence of which running water is collected in the Narra, but, except under extraordinary circumstances, is seldom in sufficient quantity to reach the sea. The river Narra extends in a south-south-eastern direction to Omerote, skirts the Thurr or Indian Desert. South of that place the river is called Poornam, and receives a supply of water from another river which joins it at that place. About 60 miles above the Narra enters into Poornam, and sends two branches to the Poornam under the name of Goomee. After this succession of water the Poornam has a well-defined channel from 12 to 20 feet deep and from 000

A 2
to 1300 feet wide, but it is obstructed artificially by bunds and naturally by sand-drifts. Further down the channel of the river it is divided by a chain of potholes, salt-water, and partly separated from Sindree Lake by the Alla Bund. The Alla Bund (Embankment of God) is an immense mound, nearly four miles in width and more than fifty in length, which was formed by an earthquake in 1819, the consequence of a convulsion of nature having depressed a large tract of land south of it, which, being filled with salt-water through the Lacoo Creek, now forms an extensive lake. This mound appears to be cut off from the plain by a mound called the Koroee, but in 1826 an extraordinary flood passed down the Narra and Poorumun, and, forcing a narrow passage through the Alla Bund, found its way into the Sindree Lake, and swell up the mouth of the Indus.

About 28 miles south of Buhar the Indus throws off another branch on the right, which is called the Western Narr. It runs about a hundred miles, expands towards the end of its course into the lake of Munchur, and re-joins the river near the town of Sehwan. About seven or eight miles above Hyderabad, at Meanees, occurs the third bifurcation of the river. The eastern branch, called Fulattees, runs southward and receives a considerable supply of water, which however is greatly diminished by the numerous canals which branch off from it. In the lower part of its course it is called Goonree, and sends off two branches to the Poorumun river. It enters not this branch reach the sea except by the last-mentioned river.

The Indus divides again south of Jurrakh, near 25° 27' lat. The eastern smaller branch is called Pinjeees, and below Mugrebee it is called Goonga. It has always water enough to be navigable for flat-bottomed boats, north of the bund at Mugrebee, and even below the dam it is a running stream. It enters the heavens the banks of it are considered as the harbour of the delta, and much frequented. On the bar are fifteen feet of water at high tide, and a depth of four fathoms all the way to Vikkur, even when the tide is out.

The western branch of the Indus is the Buggaur. It leaves the Satar below Tatta, and runs in a general course due west, but with several large bends. About twelve miles from the sea it divides into two branches, of which one runs south-west; it reaches the sea by the Pietaeeen mouth. The other arm runs west-north-west, and disembogues by the Piteeet mouth. Both of these arms divide several times before they reach the sea, and they enter it by several mouths. The two large channels are navigable for sea-boats of fifty tons, but as they are beset at their mouths with sand-banks, which overlap one another, the navigation is intricate and dangerous; still a few boats ascend them to Darajoe.

The Indus, with the exception of the mouths, which, as above mentioned, are accessible for sea-boats, can only be navigated by flat-bottomed vessels which do not draw more than four feet of water when heavily laden. The largest carrying about seven hundred tons, are considered as the largest vessels safe for the river. They are built at the towns along the coast, and the passage of the town of the bed of the river are subject to frequent changes, and large portions of the banks frequently fall down into the water, having been washed away by the current.

Surface and Soil.—The Delta, or that part of Sindie which is enclosed by the Satar and Baghaur branches, has an alluvial soil consisting of successive layers of earth, clay, and sand. As the greater part of the river is cut off from the sea, and the current, on account of the abundance of green forage, which furnishes pasture for large herds of buffaloes. At the back of it extends a belt ten miles in width, where the country is so thickly covered with brush and bushes, even as far as the Poormun. The rice land which lies at the back of the sugar-cane, which yields a coarse kind of sugar. The soil in many parts is impregnated with saltpetre, which is extracted, but not exported, as formerly. The climate is sultry and oppressive in the summer, and in the winter it is cold, but the wind is a gale. If we except a few small towns and villages, the inhabitants reside in temporary villages, which they remove according as they are compelled by the increase of the inundation of the Indus and its tributaries.

That extensive tract of country which lies west of the Indus, and extends from the sea-shore to the town of Sehwan (20° 27' N. lat.) has a different character. It is only along the banks of the river that there is a low alluvial tract, a few miles wide, which can be cultivated, as it has the advantage of being irrigated by short cuts from the river. Beyond its limits the country rises higher, and the soil is gravely and intermixed with pebbles, and soon passes into low hills composed of sandstone. Their height seldom exceeds two hundred feet; but in approaching the Hula Mountains they rise much higher, and form several short ranges, of which the Narra branch of the Indus flows between; the western of these ranges are laid down in our maps. The small rivers which drain this hilly tract have only water for three or four months; but during the remainder of the year abundance of water is found in pools in the beds of the rivers. The soil is clay, and gravel mixed together, but they are not cultivated. In these parts are no fixed villages, the country being inhabited by nomadic tribes, whose wealth consists of camels, sheep, goats, and buffaloes; the Hula Mountains, which lie between this tract and Beloochistan, are barren and almost without vegetation.

Proceeding on the same side of the Indus, north of the town of Sehwan, we enter one of the most fertile districts of Sind, which extends some miles north of Shikarpore. The country is level, and the means of irrigating the land are abundant; for besides the main channel of the Indus, which is used for irrigating the adjacent lands, the interior of this region, for the greatest part of its extent, is traversed by the Western Narr, which parlates the inundations of the principal river, and at some places connected with if by transverse canals. The lake of Munchur extends about eighteen miles from north-north-west to south-south-east, and is about eight or nine miles across. In the dry season its waters are brackish, in the rainy season they are dry, and yield very rich crops. That part of the plain which lies north of the place where the Narra branches off from the Indus, derives the same advantages from the deep water which is high in the rainy season, and extends fifty miles inland, until it joins the Narr, after passing near Shikarpore. The principal articles of cultivation in this plain are cotton, sugar, and rice. Large droves of buffaloes, cows, Excellent sheep, and goats, are pasturing on the country. Various kinds of trees of great size are found in many places, and yield plenty of timber for the construction of water-wheels and for other agricultural purposes. The river, as well as the lake, is navigated by boats.

The plain properly extends farther northward to the boundary-line of Sind; but north of Shikarpore it attains a higher level, and as there are no canals, irrigation is not practised. As however the soil is very good, which is shown by the excellent pastures and large trees, this tract would also yield abundant crops if it was well protected against the predatory tribes which inhabit the adjacent Murrrees and Beloochistan. But these tribes have the last in subjugation of the cultural population and taken possession of the country, in which they wander about with their herds of buffaloes, sheep, and goats.

The country on the east of the Indus, from the northern boundary-line to the parallel of Hyderabad and Omercorse, presents a different aspect. The banks of the river to the distance of two or three miles inland are covered with tamarisk and salt-thorn; the soil is sandy and waternod, and is cut by canals, which carry the water of the river to the back country. On the edge of this back country the villages are built, and generally raised somewhat above the ordinary level, to avoid the inundation of the meadows. To these villages are carried by numerous canals. They are generally cut in those...
parts of the river which run east and west, that the water may be thrown south into the interior. Some of these canals are of great extent. One of them, called the Meerwah, conducts by a southerly course the waters of the Indus from the north coast of Sindh to the southern region, where they are lost in sands or dispersed over the fields. The soil of this tract is alluvial, with the exception of a small rocky district which crosses the Indus at Bahbur, and extends on the western side of the Ganges. The soil of all the canals is fringed with a broad agricultural band, on which numerous large villages are built, many of which contain 500 houses. Besides the canals there is a canalast river that meanders northward by which the produce of the soil is carried. In the fair season, when dry, they become the beaten footpath of the people and are excellent cart-roads. Beyond the reach of the water, the cultivated tracts are hard and sandy. Dry and cracked from the heat of the sun, the loosened sand is raised by the prevailing westerly winds into little hillocks from twenty to thirty feet high, which gradually assume the appearance of a desert running imperceptibly to the Thurr. Only at a few places grass is cultivated, as its growth depends on rain, which is very uncertain in these parts of Sind. The lower parts of the uncultivated ground are generally overrun with tamarisk jungle.

The country south of a line drawn from Hyderabad to Quetta, where the Hindu and the Arab tribes of the southern region of the Indus, generally resembles the region just noticed. In its most northern corner, where the Indus and its Fullaloe branch run nearly parallel, is a low ridge of rocks which extends for several miles. In its eastern end, several isolated hills of limestone, of moderate elevation. Except these hills the country is flat and well cultivated in the vicinity of the numerous canals, which bring to the interior the waters of the Sathe and Empigen stream. Between the Indus and Jhang is a tract of wilder country, where the Poroom a considerable extent of country is covered by a salt-marsh. The country near the last-mentioned branch of the Indus is little cultivated, except in the vicinity of the Goomee river. Towards the east, its course is a complete desert, resembling the Rumm. There are hardly any plants met with, except a saltine plant called darre, which forms the principal food of the camels in this uninhabited country. The soil is of such a description as not to absorb water, which therefore remains upon the level surface until it is carried off by evaporation. Indifferent water may be obtained in many parts of this desert by digging wells to the depth of eighteen feet. This sterile tract extends twenty miles from the sea and the Koorai mouth of the Indus to the north-eastern part of the peninsula of Gujarath, a distance of about 200 miles; in breadth it is about 85, but there are various belts and ramifications, by the addition of which its area is increased to 7000 square miles. It is a perfectly level tract, on which no fresh water exists, and not even the most stunted vegetable. The soil is a mixture of mud, sand, and clay, and is covered with a thick incrustation of salt in the dry season, and during the south-eastern monsoon. This, with the effect of working on the common level of the sea, it is lower than the adjacent country. The southern banks are in many places very fertile, but often sandy, and only partially cultivated. On these water of excellent quality is found within a few yards, and tanks of rain-water, within 200 yards from the Rumm itself, retain their sweetness for many months. There are also some islands in the sea for which occurs, but it is scarce. By some the Rumm has been called a marsh, but it has none of its characteristic: it is not covered or saturated with water, but at certain periods it has neither weeds nor grass in its bed, which, instead of being aluny, is hard, dry, and sandy, and of such a consistncy as never to become clayey; nor is it otherwise fenny or swampy. That singular phenomenon called mirage nowhere produces such delusions as in this tract; the smallest shrub at a distance assumes the appearance of a forest.

Climate.—The climate of Sind differs greatly from that of other parts of Hindustan. Though the south-west monsoon from the Arabian Sea begins to blow in April, and the heavy rains from the Himalayas begin to fall in June, the latter do not commence to rain the Indus till the end of June or the middle of July. There are also heavy falls at the vernal equinox. The delta frequently suffers from dearth, and sometimes for several years together, but the dews are heavy.

In Upper Sind (Kohistan), that is, north of Hyderabad, the natives of the country divide the year into three seasons, the spring, the hot season, and the cold season. The spring is of very short duration. The cold of the winter continues to the end of February, whilst the heat which commences in the middle of March is so intense, that it is but little exceeded by that of the following months. The temperate weather therefore between the extremes of the cold and hot seasons is very short. The hot season, which may be considered as the heat of the middle of March, and it continues generally without intermission till the end of August or the middle of September. The storms of thunder attended by rain which occasionally occur in June or July afford a brief respite from the heat. A curious phenomenon is observed in this country on the setting in of one of these storms, it being always preceded for two or three days by a close atmosphere loaded with a fine description of subterraneous atmosphere, which produces a thick fog. But immediately previous to the bursting of a storm the air is literally darkened by immense volumes of sand driven in black masses before the wind, and obscuring the whole surface of the country. These sand-storms, which bear a great resemblance to the pampberos of Buenos Ayres, appear to be the natural effects of the desert countries surrounding Upper Sindo, over which no violent wind can pass without raising clouds of the shifting sands which cover their surface. The heat of Upper Sindo from the middle of April to the end of July is said to exceed that of any part of India, and the thermometer rises sometimes to 120° in the shade. The hot southerly winds which then prevail bring a greenness and a freshness even to the most barren tracts of the land, and the sand-storms, which rise from the sandbeds of the Indus, present a most arid appearance, which is only relieved by the appearance of the river lying much of the country on each bank under water. In September and October, when it leaves the country, the water quickly dries up, and leaves a dry and cracked soil, except in those tracts which have been cultivated.

During the cold season, from October until the end of February, the climate of Upper Sindo is pleasant and salubrious. Frost occasionally occurs, but the first snow which appears in the mountains generally assumes the appearance of winter in the northern climates. The setting of the cold and violent northern winds of November stops all vegetation except a few stunted...
tamarisk and babool bushes. Frost and blighting dew follow, and tend also to destroy a great portion of what otherwise would have been germs of vegetable life, which, if they chance to escape, rise only to be annihilated by the heats of April and May. The crops of Upper Sind are, therefore, early fail in its effects, not only to the European, but the native constit-
ution, and during certain periods of the year exposure to it is as much as possibly avoided by the people of the country.
At the country is only lately become accessible to Eu-
ropians, we have not yet received any series of meteorological observation extending over a whole year. But we have ob-
servations made at Kureechee on the sea-shore, and at Sukkur in Lower Sind for seven months in 1844, and the result of
them is very interesting.

Easter. This difference is to be ascribed to the desert countries by which Sukkur is surrounded. At this time of the year (April) only six months during which the hottest months is three or four degrees more intense than at
noon. This is so entirely to be ascribed to the hot southerly
winds, which invariably continue to blow with considerable force till midnight.

**Productions.**—Sind is rich in productions. Though its
botanical wealth is not great, the agricultural products are nu-
merous; all the grains and pulse common to India are
grown. Rice is the staple in the delta and liminities in the
country between the Western Narra and the Indus, but in the
other parts wheat and jooware (large maize) are most closely cultivated; next to these Holca is spicata and Phascolus mungo.
Barley is grown in some districts; other articles are,
Phascolus maximus, Errum lens, Pariwm italicum, and Cicer arietinum.
Indigo is largely grown in the north-eastern districts, but it is inferior to that of Bengal.
Ox is cultivated near Sirkhapore, and in some other districts.
The sugar-cane is pretty generally cultivated throughout the whole
of the province, but its produce is inferior to that of Northern
Hindustan and the Punjab. Cotton is cultivated everywhere, but the staple of the northern parts is the cotton of guage. Quality is grown in the vicinity of Khypoor. Hemp, cumin-
ners, water melons and musk melons, are extensively culti-

Garden produce gardens, turnips, radishes, onions, and several kinds of pumpkins, the egg-plant, three
kinds of beans, peas, the *Monardia charnna*, oil, and mustard.
The root of the lotus, which covers a great portion of the Lake of Munchar, is eaten. Sesamum, garlic, capsi-
cum, and turmeric abound, and the last is used as a dye.
Among the fruits are the date, mango, pomegranate, apple,
grape, lime, citron, fig, apricot, pistachio, and Keara nuts,
several kinds of wild plum, and the tamaraad, but most of these are of an inferior sort, and much inferior to those of Cabool. About Shikarpore and Bukkur the dates are so plentiful as to constitute the principal food of the lower classes, but they are inferior in size and flavour to the Arabian and Egyptian dates, though superior to those of Northern India.

The tamaris is the most abundant production of the uncultu-
ward, and almost as useful to the inhabitants as the bamboo to the native of India. The flowers form an article of export to Persia and the Punjab under the name of anseer. When dried, pulverized, and infused in water, they yield a red fluid in which cottons are steeped to prepare them for
dye. The wood supplies the inhabitants almost exclusively with the material of their houses, the construction of houses, boats, and agricultural implements. The boughs are used for fences and cattle-sheds, tall lines and to thatch houses, and are placed into baskets and mats for boats. The young shoots form a nutritious food for goats and cattle.

Dromedaries and asses constitute the principal means of conveysance by land. The dromedaries are reared in great
numbers, but they are not equal in strength and size to those of the neighbouring countries. The horses of Sind are small
but hardy, and capable of bearing the greatest fatigue. The
horses and asses are imported from Afghanistan and Persia. Mules are only kept at a few places. Immense herds of buffaloes graze on the banks of the Indus and its arms, and at other places common. Other and hides constitute an
important article of export. Sheep and goats are met with almost everywhere in Upper Sind, and wool is exported from that tract which lies west of the Indus and north of Shikarpoore.

Fowls are plentiful in some places; and tigers, wolves, jackals, wild hogs, porcupines, deer, and hares live in the woods. There is only seen north of Sukkur. Hogs are very numerous, and very destructive to the fields. Among the amphibious animals are the alligator, otter, and badger. Badger and otter skins form an article of export to Afghan-
istan. Snakes, scorpions, and centipedes abound in rocky
situations. Among the birds are a peculiar kind of myrropy, or bee-eater, the black partridge, the grey partridge, the quail, two kinds of woodpecker, the razor-beak, several
kinds of gulls, the pelican, and a species of plover. Geese, ducks, divers, and other water-fowl are plentiful on the banks of the Indus and those of Lake Munchar, as also on the swampy

In the Murree and Boggie hills, a species of the Suliman range, sulphur and alum are found, and form articles of trade.
In the delta and other places the soil is impregnated with salt, and some is collected for home consumption. Not a stone of marble is exported from Sind to Bukkur and Roeere is found in the level parts of the country.

**Population and Inhabitants.**—Sind is a thinly peopled

Sind is divided into three distinct classes, the Sindees, the Beloochoos, and the Hindu. In all the larger
towns Hindus are most numerous, but in the smaller villages and agricultural districts the Sindees and Beloochoos form the
bulk of the population. The Hindus are divided into four classes, the aborigines to 600,000, and the Beloochoos to 300,000. The
first are occupied entirely in trade; and in religion, as well as in
habits, are perfectly distinct from the two latter, who are
Mohammedans, agriculturists, the Beloochoos and the Sindees as servant, yet there are many villages throughout Sind wholly composed of natives, and others which are
termed Belooch villages, from being the sole property of that
nation. The Sindees are the less fixed part of the popu-
lation, being scattered over the whole country, whilst many
thousands lead nomadic lives, moving their villages with the rise and fall of the river Indus; they are also boatmen and fishermen. The Sind dees are divided into those who are

*Digitized by Google*
Divisions and Towns.—Sind is divided by the natives into two parts: Lar, which comprehends the southern portion as far north as Sehwan; and Sirs, which extends over the northern portion of the country, Shah-Bunder, Vikkur, and Kurachoo. Shah-Bunder, built on the Mull mouth of the Indus, is a small place, accessible for sea boats of 25 tons burden; it exports rice. Vikkur, situated on the Haurmooe mouth, 25 miles from the sea, is larger, the river being navigable to that place for more than 35 miles for sea boats of 40 tons burden; it exports the produce of the delta. Kurachoo, on the west, and about 30 miles from the sea, is a barren spot, but on the opposite side, the Pitto, is built at the head of a creek, distant from the sea four miles. A harbour, at its entrance protected by a high headland, affords safe anchorage at all seasons to vessels of 300 tons, from whence large boats can pass close up to the town, which is built on a slightly rising ground and surrounded by a mud wall. The bazaars are extensive, but the streets are narrow and filthy. The inhabitants amount to 14,000, and carry on an extensive trade by sea with India, Arabia, and Persia, and by land with Shikarpore.

Hyderabad or Haidarabad, the present capital and seat of the government, is built not far from the east bank of the Indus, between this river and a large Palwash creek, on a rocky eminence. It has no remarkable buildings, and the population, amounting to nearly 30,000 individuals, live in mud huts. Nearly half-way between Hyderabad and the Haurmooe mouth of the Indus, is the town of Shikarpore. Tatt, a large and populous town, the capital city of Sambus mentioned by Arrian. [Alexander, P. C., p. 301.] It appears that at this time the country was divided among a number of independent sovereigns. Nothing is known of the period from the death of the Mughul emperor Muhammad of Ghizni to the year 1748, when Shah Nadir founded the kingdom of Afghanistan, and was annexed to it, but the government of the country remained in the hands of a Bolochee family, the Kalhors, who before that period had settled there and acquired great authority. Among the other Bolochee tribes settled in the country was that of the Talpoorees. Their chief, Byram Khan, was minister of Mirjan Suruswar Khan, the Kalhor ruler, and was with one of his sons cruelly put to death by him in 1776. His death produced violent disturbances in Sind, owing to the extensive influence which he had with his tribe and the country. In 1781 Bejar, another son of Byram Khan, bore arms against his father and was put to death. Shah Nadir Khan exasperated the Talpoorees, who rose in a body, and having dethroned the tyrant, raised Futtih Ulee, the grandson of Byram and chief of their tribe, to the government. Timur Shah was a brother of the sole survivor of the Bolochee family, was put to death. After that, Sind was tributary, and having dethroned the tyrant, raised Futtih Ulee, the grandson of Byram and chief of their tribe, to the government. Timur Shah was a brother of the sole survivor of the Bolochee family, was put to death. After that, Sind was tributary, and having dethroned the tyrant, raised Futtih Ulee, the grandson of Byram and chief of their tribe, to the government. The Talpoorees divided the country into three unequal parts, and each of the three families of which it consisted received a portion of the country. These sovereigns were called Amers.

When Shah Shoajah had lost the throne of Cabool, these sovereigns considered themselves as quite independent, and when in 1834, when he came to Cabool to recover it, they opposed the march of his army through their territories. But he beat them in a battle fought seven cones from Cabool, and obliged them to pay seven cones of rice to the British. The Talpoorees of Shikarpore. Meanwhile Sir Alexander Burnes had visited Sindo (1831) and a treaty of commerce had been concluded between the Amers and the British government, by which the British was given the right to sell goods to the country and to purchase all the goods of every description manufactured in the principal towns and villages, chiefly for home consumption, and a little is exported to Afghanistan and Persia. Among the silk manufactures the languis, a rich fabric of silk, cotton, and gold, variegated in texture, are the most common. The languis are manufactured in the villages of Ranopee, Giambat, Koornah, and Durns, situated near one another, south of the town of Khypore. They are chiefly of silk with cotton borders, or a few of silk and cotton mixed, and inferior to those of Tatta and Bhowal-

(In 1841), a spirit of insurrection manifested itself in Sind to among the Beloochee tribes, which however subsided when the British army had again advanced into Afghanistan. As the navigability of the Indus for flat-bottomed steam-boats was now ascertained, the British wished to retain the places in Sind where they were still in their possession, and they attempted to establish a firm and permanent new treaty. The Ameer, finding their inability to resist, were willing to grant the proposed conditions, except one, that is, to permit a track-road to be made along the banks of the Indus, because such a road would destroy their shooting-ground along the river. They had here immense enclosures for the chase of wild animals; these enclosures were called shikargars. It was however soon evident that this was only a pretext for breaking the treaty and taking the narrow track-road along the river, required for a track-path, would have not only diminished the immense extent of their shikargars. The negotiations were scarcely broken off, when an army of 22,000 Beloochees was ready to attack the British, and to expel them from Sind. Sir Charles Napier, who commanded 3000 men, British and native troops, stationed at Bukkur and its vicinity, immediately put them in motion. He found the army of the Ameer near Meeanee, a place near the spot where the Falulee branch leaves the Indus. On the 17th of February, 1843, an obstinate battle was fought at Meeanee, between the British troops and the Beloochies, in which the latter were completely defeated. They lost 5000 men, all with their artillery and military stores. The Ameers, six in number, came to the British camp and surrendered unconditionally. On the 10th of March, the capital of the Ameer was taken, and the possession of the British. The Ameers were removed to Bombay and received liberal allowances. Thus Sind became a portion of the British empire in India. Partial insurrections still continued among some of the Beloochini tribes, but the activity of the governor of Sind, Sir Charles Napier, has put them down, and Sind begins to enjoy that peace and prosperity which the British army has conferred on or secured to other parts of Hindustan.

SINGLETON, HENRY, was born in London, 1766. His father died while he was an infant, and he was brought up by an uncle, William Singleton, a miniature-painter, who gave him a good education. In 1786 he was in Paris, where he also were favourite studies with him. At the age of eighteen he obtained the first silver medal for drawing in the Royal Academy; and in 1788 he obtained the gold medal for the best painting of the 'Ode to the Nightingale.' At the age of twenty-five his 'Ode to Alexander's Feast.' The medal was presented by Sir John Reynolds, the last time but one that he presented at the distribution of the Academy prizes, and he is said on the occasion to have congratulated him 'in terms of mercurial Mockery.' Singleton painted portrait and history. The first remarkable picture which he produced was a large portrait piece of all the Academicians assembled in the Council Chamber; this picture is now in the possession of the Academy; he was however passed over, and he had too much pride ever to make a second attempt. He lived in the early part of his career in Norton Street, but removed in 1794 to the Haymarket, where he remained till his death in 1839.

Singleton was versatile and ready in invention, though his style of drawing was uniform; and both his pictures and his designs were very numerous; he was an eminent miniaturist and publisher. West has been heard to say—"Propose to Singleton a subject, and it will be on canvas in five or six hours." The rapidity of his work is very great, he compiles figures of almost every class; many of them have been engraved, and some on a large scale. Among his best works are Christ entering Jerusalem; Christ healing the Blind; John Baptising; Coriolanus and his Mother and Hannibal shriving earnestly to the Roman; which have all been engraved on a large scale in Mezzotinto: further, the Storming of Seringapatam; the Death of Tipoo Saib; and the Surrender of Tipoo's Sons; of which there are large prints by Schiavonetti and Cordon. In his later years he was almost wholly employed upon a large series of illustrations from Shakkapere, which are his principal works: the series included twenty-two plates, and all the engravings of Shakkapere seem to be taken from the favourite dramatic representations of Shakkapere which in Singleton's time were so abundant. He died on the 15th of September, 1839, and was buried in the vacant grave in the churchyard of St. John's Church about thirty years before. (Art-Union Journal, 1839.)

SI PHON BAROMETER. This instrument, which was invented by M. Gay Lussac, is very briefly indicated under Barometer. P. P. and a description of the tube is given in fig. 14 of that article; but, as this kind of barometer has of late been much employed (several of them, for example, were used by Col. Mudge and Mr. Featherstonaugh in determining the atmospheric pressure along the route of the North America from the Penobscot and St. John's rivers to the Bay of Chaleurs), it may be advantageous to introduce here a short notice of the construction of the instrument.

The tube is hermetically sealed at both extremities, the end a, in the figure above referred to, being closed after the mercury is introduced, and at a perforation is made, which is so small that, while it allows a communication between the air within and without, it does not, the affinity of mercury for glass being inferior to that of the particles of the fluid for one another, permit the mercury to escape. A scale of inches, each of which is divided into twenty equal parts, is placed by the side of the tube; and by means of a groove at b, the tube is subdivided into twenty-five equal parts. In the French Siphon Barometer the scale is divided into millimetres (each of which is subdivided into ten equal parts), and a microscope, each of them is divided into one hundred equal parts. Two indices with verniers are applied to the scale, by one of which (at p) is read on the scale the graduation corresponding to the top of the mercurial column of the tube, and by the other (at q), is read the graduation corresponding to the top of the column in the longer branch. The zero of the scale is either between these indices or below the lowest of them; in the former case the sum and, in the latter, the difference of the readings is the true height of the mercurial column.

The siphon barometer has an advantage over those of a different kind in requiring no correction for capillary attraction, since such action equally affects both extremities p and s of the mercurial column: it is extremely light, and is easily brought to a position proper for the observation, but it requires very careful attention of the sights of the instruments. It is necessary to avoid inventing it suddenly, since the glass is liable to be broken by the weight of the mercury when the latter strikes against the end of the tube.

SIPHON, GAUGE, in Pneumatics, is a tube of glass bent so as to form two branches equal and parallel to one another, and each from 6 to 8 inches in length; the tube is hermetically closed at one end and left open at the other. One of the branches is provided with a mercurial column, and the other, in vertical positions with the closed and open ends upwards, they are, by means of a brass stem terminating in a screw, suffixed generally to the under surface of the table carrying the plate to which the glass is fixed by means of copper.
closed at the lower and open at the upper extremity; and the open end of the cylinder is screwed to the table of the air-pump immediately about the orifice of a brass tube which passes directly under the orifice of the tube which, passing through the pump-plate, opens into the receiver, and the lower end being immersed in a small cistern of mercury; for the air in the receiver and that in the barometer tube having the same depression above the mercury—that is, in proportion as the exhaustion proceeds, the pressure of the external atmosphere on the surface of the mercury in the cistern forces mercury into the tube, so that, if the exhaustion within the receiver could be carried far enough, the column of mercury would stand at the same height in the tube as it stands in the tube of an accurate barometer, and would indicate a perfect vacuum in the receiver. The degree of rarefaction in the receiver is consequently indicated by the number of inches expressing the height of the column of mercury in the tube. The siphon-gauge is also provided with a scale of inches which are decimally subdivided; but, while the pressure of the air in the receiver and in the barometer tube being equal to that of the atmosphere, the deflection of the needle from the weight of the column of mercury in the closed branch, the gauge presents no indications: from the time however that, by continuing the process of exhausting the receiver, the pressure is reduced below that of the atmosphere, the deflection of the needle from the weight of the column of mercury in the other, that column descends in the latter branch and rises in the former; and then the degree of rarefaction in the receiver is indicated by the difference between the height of the columns of mercury in the two branches of the siphon.

The proof of the claim to the air-pump, P.C., and a description of which has been inadvertently omitted; was also intended to include a siphon-gauge or the purpose of determining the degree of rarefaction attained in the receiver of an air-pump. It consists of a small glass vessel nearly similar in form to a pear, or rather to a Florence flask, terminating in a cylindrical stem; the upper or smaller extremity is hermetically sealed, and the lower extremity is open. To the upper extremity of the gauge is affixed a wire which passes through an air-tight orifice at the top of the receiver on the air-pump so as to be capable of sliding up and down, carrying with it the gauge in the interior of the receiver; and under the lower extremity of the gauge is a vessel of mercury.

When the receiver has been exhausted as much as may be thought proper, the gauge is pressed down till its lower or open extremity enters into the mercury in the vessel below; at which time, evidently, the air in the gauge will have the same pressure as that of the atmosphere; but on admitting the air into the receiver, its pressure on the surface of the mercury in the vessel about the bottom of the gauge will force mercury into the latter, when the air, which, in its rarefied state, occupied the whole interior of the gauge, will be brought to the same density as that in the receiver, and consequently as that of the atmosphere, and will occupy only a small space at the upper extremity of the gauge. A graduated scale serves to show the volume of the air in its compressed state; and this, being compared with the known volume of the whole gauge, serves to determine the degree of rarefaction which had been produced by the partial exhaustion of the receiver.

At the time when the siphon-gauge and pear-gauge were invented, it was the custom to place the receiver of the air-pump on a ring of leather soaked in oil and laid on the pump-plate, in order to prevent the atmosphere from entering the receiver during the process of exhaustion; when, on the air within being rarefied, a quantity of elastic vapour extracted from the moisture occupied the receiver; now the barometer and siphon gauge have been substituted in its place, the elastic vapour, diminished by the partial exhaustion; but, in employing the pear-gauge, which, during the process of exhaustion, takes up a portion of the elastic vapour, on re-admitting the air into the jar, the vapour will condense upon the water, and the gauge shows only the quantity of pure air which is left in the receiver after the exhaustion. This discovery was made by the Honourable Mr. Cavendish on wit.

P.C. S., No. 152.

Prolonging some experiments made by Mr. Nairne, a distin
guished optician, in which it was observed that the pear
gauges always indicated much higher degrees of rarefaction
than were given by barometers or by siphon-gauges, the
business of the explanation proposed in order to account
for this discrepancy was soon afterwards proved by Mr. Nairne
by means of experiments made with the different kinds of
gauges, in which the last-named instrument, by causing a
moisture from the interior of the receiver. The pear

gauge was then found to show very nearly the same degrees
of rarefaction as were exhibited by the other gauges.

It may be observed here, that the pear-gauge is the instru
ment by which the force of elastic vapour was discovered.

SIROCCO is the name given to a hot and suffocating wind which appears to originate with the rarefied air in the sandy deserts of Arabia, in the plain of the Nile commences; it extends eastward over Arabia, Persia, and some parts of Hindustan, and it is felt, but with less inconvenience, in Italy and Spain. This wind is probably only one of the modifications of that which, in different coun
tries, is called sanoom, simoom, suban or samieli, khamaen,
and harmattan. [Samikeli, F. C.]

Under Sirocco, F. C. reference is made to the article Wind; but by inadvertence the notice was, in the place referred to, omitted.

SISMONDI, JEAN CHARLES LEONARD SISMONDI, D.E., was the son of a Protestant minister of the canon of Geneva; his father emigrated to an autocratic nation of the origin, which has become extinct by his death. His ancestors, who were attached to the Gibeillian party, were expelled from Fira in the fourteenth century, and took refuge in France, where they remained till the revolution of the eighteenth century, when they settled at Geneva. Sismondi was born at Geneva on the 9th of May, 1773. He was first placed at the College of Geneva, where he acquired a sound knowledge of classical literature.

From the college he was removed to the Auditoire, where he was enabled to pursue a more extended course of study. His education being completed, he was compelled by the change of fortune which befell his family, owing to the events of the French revolution, to enter as clerk in the counting	house of the firm of Eynard and Co. at Lyon. Filial obedi
ence induced him to undertake a duty to which he was un
fitted by his previous habits, and which the highly cultivated
disposition of his mind rendered scarcely supportable. The moral training, however, which he underwent in mastering the difficulties of his new situation, and in the regular discharge of its duties, produced an effect which, in after life, he acknow
ledged to have been eminently beneficial to him. He became so

there, they determined upon emigrating to the country of their ancestors, and arrived at Florence in October, 1798.

They invested the produce of the estate which they had sold in purchasing a small farm at Valmondo, near Piacenza, a farm which had been selected by the young Siomodi. Here he divided his time between the active superintendence of his farm and the preparation for his history which he had projected during his travels.

'Récherches sur les Consulaires Italiens des Premiers Legers.' These works, though they have not been published, are generally regarded as the groundwork of his subsequent historical works. The first, which he adopted for his history of Italy, has been revised, amplified, and illustrated in the work of M. de Toquereille on the democratic governments of America. In 1801 appeared at Geneva the first published work of Siomodi, an essay written during the last part of his stay in Italy; it was entitled 'Tableau de l' Agriculture Toscane.' To his study of this subject may perhaps be attributed the prominence which, in his writings on political economy, he gives to agriculture. Eminently practical in this detail, this interesting treatise discards even the appearance of theory, and contents itself with portraying in true but lively colours the actual state of the country and the manner of life of its inhabitants. The year previous to the publication of this work Siomodi and his parents had again returned to Geneva, where they lived on the remnant of a once large property, which his father had sacrificed to his confidence in the future of a new Necker in [Napoleon]. He published, in 1808, his essay on political economy, with the title 'De la Richesse Commerciale, ou Principes d'Economie Politique appliquee à la Legislation du Commerce.' This work he had been writing for forty years. In 1810, he published, under the title 'Nouveaux Principes d'Economie Politique,' the views of Adam Smith [Smith, ADAM, P.C.] are almost implicitly followed in this treatise, and, as they happened to coincide with the popular notions on the subject, they brought the writer into repute. The vacant chair of political economy in the university of Wille was soon after offered to him by Count Flättner, who came purposely to Geneva to urge in person his proposal. Though the offer was advantageous in a pecuniary point of view, and the acceptance of it on that account urged upon him by his parents, it was declined by him from his dislike to teaching. It was at this period that Siomodi began to apply himself in earnest to historical investigations, and, by the advice of his mother, a woman of cultivated mind and sound understanding, to devote himself chiefly to the study of history.

His residence at Geneva, though it was enlivened by his enjoying the intimacy of several literary persons, such as Benjamin Constant and Madame De Stael, could not deliver him from the desponding feelings which are so common to the most philosophical of our contemporaries. The suggestion of his recent mother, he was induced, in 1805, to accompany Madame De Stael in a tour through Italy. Sympathy of literary tastes had been his chief interest in life, and these two distinguished writers; the influence of the scenes they visited together in that classical country, and the poetic charm cast upon them by the conversation of the authors of 'Corinna,' [KRAIN, ADOLPHE GABRIEL, P.C.], fixed the determinations of Siomodi to consecrate the past glories of the land of his ancestors in the page of history. The first-fruits of his historical studies appeared in the first two volumes of his 'Républiques Italiennes,' which were published at Zürich, in 1807. His publisher, Gremer, is stated to have dealt hardly with him, and the publication of the subsequent volumes, the last of which appeared in 1816, was transferred to Tresselt and Wirtz. A new and more complete edition, in sixteen volumes, appeared during the years 1825 and 1826, both at Paris and Brussels. In the composition of this his first and most important historical work, Siomodi has been blamed for the want of sufficiency as a source of information, and in his want of sufficient use of the collected materials of the 'Républiques Italiennes,' as a historical record, is chiefly due. The style is pleasing and attractive, but, though a good French scholar, he never hesitates to use an unauthentic source of information, and to make his own construction of the meaning with greater precision. The part of the work, which is generally considered to be most defective, is that which treat of the development of the republican constitutions and the modifications which the French Revolution have introduced into them. His Régolaires, published, in 'Laude's Cabinet Cyclopaedia,' an abridgment, in English, of his 'Républiques
Italiennes; a French edition of this work appeared in Paris in 1832, under the title "Histoire de la Renaissance de la France et de l'Art Italienne." The last and least known of his historical works is entitled "Histoire de la Chute de l'Empire Romain et du Déclin de la Civilisation." This work, which was published at Paris in 1841, and in a second edition in 1844, sold by subscription for 1000 francs. The other writings of Simondi are, 1. "Julie Severa," an historical novel in imitation of Sir Walter Scott, in which he describes the condition of Gaul at the time when Rome was a power. This work was published at Paris in 1816. 2. "Etudes sur les Sciences Sociales," published at Paris in 1836; this work contains a collection of articles which he had previously contributed to various periodicals: 8. "De la Vie Contemporaine," ed. 8vo, Paris, 1827. The above is a brief account of the writings of Simondi; but it would be doing injustice to his memory to omit some of the details of his private life and character which have been recorded by his biographers. Surrounded by a circle of all that was most distinguished in literature, he was conspicuous among them for the amiability of his disposition and the devotedness of his friendship. Though he never reached a state of affluence, he was liberal in contributing to the necessities of the poor, and he is said to have spent considerable sums in the furtherance of causes which had political freedom for their object. Fond of society, he never allowed his inclinations to obstruct his studies. His travels were of great advantage to him in his political opinions, and he was careless of the unpopularity this conduct often entailed upon him.

About the year 1840 he felt the first symptoms of the cruel malady by which he was to be watched, which was cancer in the stomach. A short journey which he made to England appears to have aggravated his disease; but his sufferings, though intense, scarcely interrupted his application to study, and he was almost said to have written with pain in hand. Indeed three days before his death, which occurred on the 25th of June, 1842, he was occupied in correcting the last proof sheets of his "Histoire des Francais." Simondi married, in 1819, Miss Allen, sister to the late Mr. Allen of Cressify, member of parliament for Pembroke shire, and to the second wife of Sir James Mackintosh. [MACKINTOSH, Sir James, P. C.]

The following extract, which we translate from the conclusion of "L'Histoire des Francais," will be found an interesting supplement to this biographical sketch of Simondi: — My life has been divided between the study of political economy and the study of history; and, in this long narration of events, the political economist will ever be discovered conjointly with the historian. I have endeavoured to prevent those lessons being lost which experience has given us on the causes which contribute to the creation of those events, and without which we must have remained a nation of pens in hand. I have always looked upon wealth as a means, not as an end; I have always respected it, whether it really advanced the well-being of all classes, and I trust my readers will be enlightened by my criticism. I have taken in the welfare of the cultivator of the land, in the artisan, and in the poor, who has to earn his bread by the sweat of his brow, that all my sympathies belong to the needy and suffering classes of the community.

SKIN, DISEASES OF. The healthy functions of the skin and its structure have been described under SKIN, P. C. Most of the diseases of the skin have been described in this work under the head of their particular names. In this article we shall supply an arrangement of them, and a description of those which have been omitted. The following arrangement is that adopted by Bayer in his work on diseases of the skin.

Class I. Inflammation of the Skin.

Class II. Cutaneous and Subcutaneous Congestions, and Hemorrhages.

Erysipsis, Vibesus, Pustulosis, Purpura Hemorrhagica, Eczema, Dermatitis.

Class III. NEWBORN DISEASES OF THE SKIN.

Necrosis, Dilatation, Affection of the sensitivity of the skin, without appreciable alteration in the texture of this membrane.

Class IV. ALTERATIONS IN THE COLOUR OF THE SKIN.

Order 1. Alarisation. — Leucophaia, partial, general; Chlorosis.

Class V. MORBID SECRETIONS.

Ephiderosis, Acne, Folliculosis Tumours.

Class VI. DEFECTS OF CONFORMATION AND TEXTURE.

Distortion of the Skin. Cicatrizes, Vegetations, Nervus haemorrhoidalis, Subcutaneous fibres, of the skin, political opinions, and he was careless of the unpopularity which this conduct often entailed upon him.

About the year 1840 he felt the first symptoms of the cruel malady by which he was to be visited, which was cancer in the stomach. A short journey which he made to England appears to have aggravated his disease; but his sufferings, though intense, scarcely interrupted his application to study, and he was almost said to have written with pain in hand. Indeed three days before his death, which occurred on the 25th of June, 1842, he was occupied in correcting the last proof sheets of his "Histoire des Francais." Simondi married, in 1819, Miss Allen, sister to the late Mr. Allen of Cressify, member of parliament for Pembroke shire, and to the second wife of Sir James Mackintosh. [MACKINTOSH, Sir James, P. C.]

The following extract, which we translate from the conclusion of "L'Histoire des Francais," will be found an interesting supplement to this biographical sketch of Simondi: — My life has been divided between the study of political economy and the study of history; and, in this long narration of events, the political economist will ever be discovered conjointly with the historian. I have endeavoured to prevent those lessons being lost which experience has given us on the causes which contribute to the creation of those events, and without which we must have remained a nation of pens in hand. I have always looked upon wealth as a means, not as an end; I have always respected it, whether it really advanced the well-being of all classes, and I trust my readers will be enlightened by my criticism. I have taken in the welfare of the cultivator of the land, in the artisan, and in the poor, who has to earn his bread by the sweat of his brow, that all my sympathies belong to the needy and suffering classes of the community.

SKIN, DISEASES OF. The healthy functions of the skin and its structure have been described under SKIN, P. C. Most of the diseases of the skin have been described in this work under the head of their particular names. In this article we shall supply an arrangement of them, and a description of those which have been omitted. The following arrangement is that adopted by Bayer in his work on diseases of the skin.

Class I. Inflammation of the Skin.

extensive, and the tendency to inflammatory action in the skin so strong as to produce pustules instead of vesicles. Such are the cases of Eczema, those forms of Eczema which are usually described by writers on diseases of the skin.— *E. scabra, E. rubra, E. impetigoinosa.* Eczema is more likely to be confounded with itch than any other disease, from which it may be distinct, and which it resembles in its manifestations on the body. In the oil-tubes, and arises from an obstruction to the perforation of their functions, which produces inflammation. The oil-tubes of the face are very liable to obstruction from the exposure to the atmosphere, and the careless use of them. It is observed tipped with a little black spot, and when pressed they give out a quantity of their oily secretion in the form of a little meagery. They were at one time supposed really to contain a very dangerous poison, but the case is either not the same, or the case with the masses of oil in question, it is now known that a little acrasis takes up its whole in these oil-tubes, and is well known to zoologists under the name of Demodex Follicularum. This little insect may then in some instances be the exciting cause of acne.

In the treatment of acne, regard must be had to the general health. It is frequently connected with a diseased state of the gastro-intestinal mucous system, which requires attention. Where it is connected with general debility from a rapid growth, or with a scrofulous constitution, tonics and alteratives with sea-bathing and regular exercise will be found of service to the patient. In the case of any scrofulous, or other disease, characterized by the simultaneous or successive eruptions of red itching pimples, scattered or disposed in groups over the whole body. In the adult what Strophulus is in the child. (Strophulus, F. C.)

Diseases of the skin are very numerous and prevalent. In the case of the majority which occur they arise from the neglect of some of the conditions necessary for the health of the skin. These conditions in general are, good nutritious diet, freely drinking water, and the use of either warm clothing, especially during changeable and cold weather; constant and regular exercise, so as to keep the skin as an extraneous organ in perfect order; and daily ablution of every part of the body, without which and the occasional use of soap it is vain to expect to be free from many forms of skin disease.

SKY is the name commonly applied to the infinite space which surrounds the earth, and of which the visible portion, above the horizon of a spectator on any part of the earth's surface, appears to have the form of a conical segment less than a hemisphere. (Estromogeous or Objecta, P. C. B.)

The atmosphere is surrounded by air charged with vapours and terrestrial particles; and by the refections which, in consequence, the rays of light experience in passing through the earth; this, as already observed, that at times when the sun is seen set behind a mountain so covered, the blue rays reflected to the spectator from the parts of the atmosphere on each side of the mountain, cause the latter to assume a blue colour, the direct light from the mountain not being strong enough to interfere sensibly with the reflected rays.

When the sun has considerable elevation, the rays of light which reach the earth's atmosphere almost perpendicularly to its surface, undergo scarcely any change of direction; but, with respect to the light from the sun which enters obliquely into the atmosphere, the violet and blue rays, or those which are refracted to have the most of the space to cover, are red rays, are partially arrested in their course, and are reflected in abundance to the earth; they thus, when the atmosphere is nearly free from clouds, give to the parts of the sky which are removed from the apparent place of the sun an azure tint.

The blue colour of the sky about the zenith increases in proportion as the sun is nearer the horizon; the rays then fall with a more oblique kind of trend upon the eye, and, at the same time, the blue rays in the beams of light
which traverse the atmosphere in directions nearly parallel to the horizon are absorbed, so that those only, as the yellow and red, which have greater momentum, arrive at the eye of the spectator; in consequence of this the sky appears on the horizon on the side which is towards the sun, appears to be highly tinted with those colours.

Many of the blue rays, after reflection from the upper parts of the atmosphere, however absorbed in passing down to the earth; and hence it is that the blue tint of the sky is found to increase in intensity as the spectator ascends above the general level of the clouds. He finds it, moreover, that these blue tints increase in intensity, or in balloons at great elevations, the quantity of blue rays which, after reflection in the atmosphere, enter the eye, are very great; and the blueness at length becomes a deep blue; they are then minute, but still apparent; they are so much as much as midday at midnight on the earth, during the absence of the moon. It is hence evident that if they were not for the insensible reflections of the light from the sun or moon, which take place in the atmosphere, total darkness would prevail from the instant of sun-set to that of sun-rise; and even during the day, darkness would ensue, so that the stars would become visible, every time that the sun is obscured by clouds.

That the blue tint of the sky is caused by light reflected in the atmosphere is abundantly evident from the fact that the light of the sky is found to be polarised: this quality in light, being of a nature to affect only the plane of vibration of that light which first made the observation, has moreover ascertained that the light of the sky consists of two parts, one blue and the other nearly without colour; and he discovered that these have been ascribed to the refraction and reflections. (Treatise on New Philosophical Instruments, p. 349.)

The hypothesis that the azure colour of the sky is caused by reflections of blue rays, was at one time objected to on the ground that the shadows of coherent objects, placed on white paper and exposed to the sun’s light, should always appear to be blue, since the part of the paper which is in shadow can only be visible by the light of the sky reflected from thence. This phenomenon is, in fact, frequently observed; but M. de Saussure, who first made the observation, has moreover ascertained that the light of the sky consists of two parts, one blue and the other nearly without colour; and he discovered that these have been ascribed to the refraction and reflections. (Treatise on New Philosophical Instruments, p. 349.)

(Treatise on New Philosophical Instruments, p. 349.)
Smith while in Edinburgh officiated at the Episcopal chapel there. In 1808 he removed to London, where he married the daughter of Mr. Pyle, the banker, and took up his residence. He became popular as a preacher at the chapel of the Foundling Hospital, and at other places. He also delivered lectures on polite literature with much applause at the Royal Institution, in Albemarle Street, and was a regular contributor to the Edinburgh Review.

Lord Erkine, when Lord Chancellor, gave him, in 1806, the rectory of Foston, in Yorkshire. In 1810 he was presented to the living of Alton in Hampshire, which was, in 1813, he was appointed by Earl Grey one of the canons resi'dentary of St. Paul's Cathedral. Except a few years when he resided at his rectory of Foston, singularly, while at which he exerted himself, in 1808. 'Letters on the Subject of the Catholicity to my Brother Abraham who lives in the Country, by Peter Pymble,' his place of residence was London, where he was associated with literary men and politicians of Whig principles, distinguished for his conversational powers, and consequently a frequent 'diner out.' It is probable however that he kept within reasonable bounds of temperance, for he lived till the age of 77. He died at his house in Green Street, Mayfair, London, Feb. 21, 1846, and was buried in the Kensal Green Cemetery. He left the bulk of his property, which was large, to his widow and his son Wyndham Smith.

The Rev. Sydney Smith published 'Six Sermons,' Edinb., 12mo., 1800; 'Six Sermons,' 2 vols. 8vo., Lond., 1809; several occasional sermons and political pamphlets; and contributions to periodicals. In 1818 he published when he himself probably regarded as the best of his literary compositions, 'The Works of the Rev. Sydney Smith,' 3 vols. 8vo., with a preface by the author and a portrait. The collection consists of 'Letters written in Edinburgh to a Friend,' by Peter Pymble's Letters, and various occasional tracts. With respect to his contributions, he observes, 'I see very little in my reviews to alter or repel of. I always endeavoured to fight against truth, and what I thought evil then I think evil now. I am heartily glad that all our disqualifying laws for religious opinions are abolished, and I see nothing in such measures but unalixed good and real increase of strength to our establishment.' When he wrote this however, 'all our disqualifying laws' had not been abolished, as may be seen by looking over the act of parliament which is reprinted under the head Roman Catholics and Jews, P.C.S.

Sydney Smith is a very effective writer; he has considerable argumentative power, united with wit, humour, and poignant satire. His style is clear and forcible, without any apparent aim at elaboration or polish. Two or three letters which he published in the newspapers shortly before his death against the repudiation of their debts by certain States of North America are as strong in argument, as pungent in satire, and as effective in style in anything which he wrote in less than 1820. [Athenæum; Gentleman's Magazine; Preface to the Rev. Sydney Smith's Works.]

SOKE BALLS. [LIGHT BALLS, P.C.S.]

SOE. [ARTIST, P.C.S.]

SOCRATES, the ecclesiastical historian, was born at Constantinople towards the end of the fourth century. He was instructed in grammar and rhetoric by Ammonius and Heliodorus, of Alexandria, and afterwards followed the profession of scholastic or advocate, on which account he is generally designated as Sozomen the Scholastic. He appears, however, to have abandoned this profession in order to devote himself to the study of ecclesiastical history. He is generally considered the most exact and judicious of the three continuators of the history of Eusebius ('Eusebii P.C.); he is less florid in style and more careful in his statements than Sozomenus (P.C.), and less correct than Theodoretus ('Theodoretus, P.C.). He is likewise the earliest writer of the three, and Sozomenus is supposed to have borrowed some what largely from him. He died in 390 or 395; it has been eluded by Epiphanius the Scholastic in his 'Historia Tripartita,' and was published for the first time as a continuation of Eusebius, by Robert Stephens, Paris, 1634, 4to. The work is a poor translation by the Presbyter Conon. The history is divided into seven books: the five last are chiefly compiled on the authority of Rufinus ('Rufinus, P.C.), and on the relations he gathered from the church of a certain part of the church. He has two first had also been composed on the same authority; but on reading the writings of St. Athanasius he found that Rufinus had omitted several of the principal circumstances in the life of this celebrated father of the church. [Athanasius, P.C.]. He therefore undertook the task of writing these books, and took occasion of inserting several valuable documents and formularies of faith which throw much light on the Arian heresy.

Though the most exact of the continuators of Eusebius, he has nevertheless allowed himself to fall into error on several important points. For instance, he confounds the Emperor Maximianus with Maximinus (i. 1, c. 1), a mistake the more common from the similarity of the names. He professes to relate the principal events which took place in that city. 'The carelessness of writers of that age,' says Fould, 'in distinguishing between a Solinum, and a Solomon (the Dec. and Fall of the Rom. Emp., c. vii, note). He is also taken also respecting the number of bishops who refused to sign the creed drawn up at the Council of Nice (i. 1, c. 8), as it appears clearly from the acts of the council and the authority of St. Jerome, Theodoret, and others, that there were only two, not five, dissentients, as Socrates asserts. His statements respecting a law passed by the Emperor Valentinian authorizing bigamy (i. 4, c. 31), on the occasion of his marriage with Justina, rests on no other known authority, and bears the semblance of a fiction rather than a fact. His account of church discipline has been severely criticized by Baronius, Fleury, and other Catholic historians; but Socrates has this point been very ably defended by Cousin in the preface of the translation to his history. 'His impartiality is so strikingly displayed,' says Waddington, 'as to make his history a valuable source of information for the student of Catholic history; but Valensius in his life has clearly shown that there is no reason for such suspicion. We may mention another principle which he has followed, which in the mind of the modern student of church history is the most pithy in the valorousness of the Novatians, though he shows but little knowledge on the subject, and confounds Novatian, who was a priest of Rome, with Novatian of Africa. [Novatianus, P.C.]

The date of his death is not ascertained. [Hist. de l'Église, traduite par Cousin, vol. ii., Paris, 1775; Fleury, Hist. Ecclesi., l. xxvi. c. 49; Waddington, Hist. of the Church, London, 1833; Moret, Dict. Historique, art. Socrates.]

SOEUR, LE, HUBERT. This excellent sculptor, a Frenchman by birth, according to Walpole, was the pupil of the celebrated John of Bologna. He came to England probably shortly before 1630, in which year he was then living in Bartholomew Close, and a son of his was buried on the 30th of July, 1630, in the same that year in St. Bartholomew the Great. Le Sour must have been a man of about fifty years of age in 1630, for John of Bologna died in 1608 in Florence at an advanced age, and Le Sour must have visited Florence and the workshops of his master. Le Sour was born at Brussels, and in 1633 he was described as a sculptor of some distinction. His work was noticed by the French nobility and by the States-General. He was commissioned to execute a monument of William the Silent, which was never completed.

In 1633 Le Sour cast the well-known equestrian statue of Charles I., which was cast in a spot of ground near the church of St. Paul, Covent Garden, but when not put up before the commencement of the great civil war, it was sold by the Parliament to a brayer of the name of John Smith, living in the city near Holborn Comyns, who had orders to break it into pieces. Rivers instead of breaking it up, buried it, and it remained concealed until the restoration. It was placed in its present situation at the expense of the Duke of Lennox, according to the order from the Earl of Denby, afterwards Duke of Leeds. The statue was made of wood and at the expense of the family of Howard-Arundel, who have still the receipts to show by whom and for whom it was purchased. The year 1633 was chosen because it was the year in which he was destroyed himself when, after the statue was set up, he found that he had omitted the saddle-pitch; unfortunately for the truth of this
story, however, the saddle-girl is there, and further, Le Soeur can never have seen the statuette up, as he must have died several years before 1676. The figure is dignified and exalted, but does not possess much character in modelling; the hinder quarters are especially void of power and motion. The pedestal was made by Grinling Gibbons. Walpole speaks of a bust at Stourhead by Le Soeur, a noble head, but it is not of the same style as the dragon à la Romaine, three feet high on a black pedestal. It is mentioned in Vanderdoort's Catalogue of Charles the First's Collection. Le Soeur executed many other bronze or brass works in England, but they are now all lost or destroyed.

Walpole, Anecdotes of Painting, etc.; English Connoisseurs.

SOLIDITY. It is a condition of solid bodies in which the particles are held together by a cohesive power of small intensity: in consequence of this, such bodies change their figures upon the application of a small degree of force; and they do not recover their previous forms upon its removal.

This condition is the opposite of hardness, in which the particles are held together by a power of cohesion so great that they cannot be separated by any force which it may be convenient to apply to them. No body in nature is known to possess either of these qualities absolutely; but in contemplating the mechanical actions of soft bodies, balls of wet clay are generally used, while blocks of wood acting against one another, or the direct pressure of a body or other heavy weight, are used to illustrate the effects of hardness. Balls of glass or ivory, or steel springs, serve to show the mechanical actions of elastic bodies. [Conduitis on Frascati or Bozzia, P. C. S.]

SOLÉN [Tribute] (n.) In antiquity, the name of the coast of the province of York on the English coast, whose affinities are somewhat uncertain. Supposed to be Marsiliaeis. (Lindley.)

SOLIDA/GO (from the Latin, to make firm, on account of its solidity, applied to the stems of plants belonging to the natural order Compositae, the suborder Cynarinaceae, and the tribe Asteroidae. It has radiant heads of flowers, the florets of the ray pale-tomentose ligulate in one row; those of the disk, tubular, with stamens and pistil, the receptacle rather acetate, the involucre imbricated, with a few scales on the peduncle; the pappus pilose in one row; the fruit terete. This genus usually resembles the Erechtites, from which it is distinguished by its pappus in a single row, and its terete fruit.

S. Virgatae, Golden Rod, has an erect, slightly angular stem, the leaves lanceolate, narrowed at both ends; the lower leaves elliptical, stalked, serrated; the raceome erect, simple, or compound; involucral scales, lanceolate, acute; the fruit dawny. This plant is a native of the woods and thickets of Great Britain, and was formerly much used in medicine. Its leaves, dried and dried in the dried state, have been employed for internal hemorrhages. It is astringent and tonic.

SOLIDITY. For the signification of this word in its strictest sense, see the article on Brigade, P. C.; but, as the word is frequently employed to designate a condition of material substance in contradistinction from liquidity, or a gaseous form, it may in this sense be defined to be a state of a body in which the particles or molecules in it are so close together that there is no certain amount of force to separate them from one another; and, at the same time, they are subject to small variations only of their mutual distances by the application of any quantity of heat less than that which would reduce them to ashes or convert them into fluids.

The expansion of solids by heat is noticed under Heat, P. C.; see also Specific Heat, P. C.

SOPHIE, P. C.; see also SPRING, P. C.

SOPRANO. InCicero, called l'Alato Ciccio, a celebrated Neapolitan painter, was born at Neorca de' Pagni in 1657. He was originally intended for the law, but having a decided taste for art, he was at first taught by his father, who obtained for his son a scholarship and a place at the University of Naples under Francesco di Maria, and in the academy of Pietro del Po. Sopranò was one of the best and most correct painters of his time; he had great variety of figures, and his compositions were frequent and free. He had also a very great facility of execution. But his style in all its varieties belonged to the elegant and ornamental; his drawing is uniform, and in a great degree merely academical; his compositions were great; his figures, which appeared at once so much in their individualities, were much in the fashion of, under the title of 'Saul.' In 1810 he produced 'Constance de Castille, a metrical Poem, in Ten Cantos,' in the style of the 'Lady of the Lake' and 'Marmion.' In 1814 he republished 'Orestes,' together with four other tragedies. Both the
velled through France, Switzerland, and Italy in 1816, in company with Mr. Elmsley and Professor Playfair. He returned through Germany to England at the close of 1817. In 1827 he published a corrected edition of his translation of the 'Georgics,' together with the original text, and the translations of De Lille, Boase, Guzman, and others, in folio, with the preface of the sovereigns of Europe, and received medals from them in acknowledgment.

When he was in his seventieth year he commenced a poetical translation of The Iliad," of which he presented copies to the British Museum, on which occasion he received the gold medal of the British Association. In 1838 he commenced the 'Odyssey,' which he finished in July, 1839.

He died December 30, 1833, in the seventy-seventh year of his age. His eldest son William, who was a colonel in the First Regiment of Guards, died in 1816, in consequence of injuries which his constitution had suffered in the Walcheren expedition and the war in Spain. His third son George, who was assistant-resident at Nagpore, in Hindostan, was killed in repelling an attack of the Pindories, November 22, 1817. Another son, Hans, who had been in the civil service in India, died in London, April 27, 1827.

Besides the works already mentioned, Sotheby published, in 1813, 1814, and 1820, Poems, "Our English Prose Writers," containing the third edition of his 'History of the English Prose Writers,' and the second edition of his 'History of the English Poetry Writers.' His last work was a translation of the 'Dunciad,' by Pope, published in 1834.

Some of his later poems made little impression on the public, and are now nearly forgotten. His thoughts are pleasing, but faint, and frequently indistinct, from the polished diffuseness of his style. He has little originality or strength, but has great delicacy and elegance of manner, and of the whole a perfect level, and overgrown with shrubs, consisting of the Eucalyptus deusta and the Tea-Tree. Towards the southern extremity of the peninsula lying west of Spencer's Gulf, especially near Flinders's Bay, the hills are low, and have an elevation of between 600 and 800 feet; they consist of sandstone, and are covered with wood. The interior of the peninsula is low and barren, but interspersed with salt-lakes. It is called Gawler's Range, and is traversed by a narrow tract which extends from Flinders's Bay, and is between the hills and the salt-lakes, and is covered by scrub, with a few small plains. There are no rivulets or springs, but between the hills are small salt-water lakes, with miscellaneous plants growing round their margins; fresh water is only found after the rains in the crevices of the rocks. The country north of Gawler's Range has not been explored.

The country situated on the western shores of Spencer's Bay is of a much better description. It contains Port Lincoln, the most extensive and the best harbour in the colony. It consists of three basins: Spalding Cove, Port Lincoln, and Boston Bay, in each of which there is not less than ten or twelve fathoms water, with a bottom of mud and sand; and the whole of holding consists of shallow water. Round these extensive sheets of water are many large tracts well wooded, and others grassy with single trees dispersed over them. It is calculated, that in the vicinity of Port Lincoln there are three million acres suitable for cultivation or pasture. The peninsula south of Port Lincoln is hilly, but well wooded, and has much good pasture ground, and also the country north of it to the distance of ten or twelve miles; but farther north the hills disappear, and are followed by a low tract which extends along the shore, and is densely wooded with brush, among which are scattered a few small patches of grass. Water is only found near a few rocky elevations. At the back of this low and rather narrow tract is a moderately elevated table-land, whose edge is broken by deep gorges into portions resembling hills. The soil is deep loam, generally presents only here and there a little old withered grass. There are no high trees, but patches of scrubby bushes, and a few small plains. No water has been discovered.

The southernmost flowers, and the highest heath, are at the head of Spencer's Gulf, where a rather narrow low tract separates it from Flinders's Range. This tract is quite level, and has a sandy soil almost without vegetation. Flinders's Range constitutes the western extremity of a mountain chain of considerable extent. It occupies in width a space more than sixty miles from west to east, lying east of Spencer's Gulf. It may be said that this mountain tract terminates on the south of the banks of the Murray, and on the north of the River (25° 30' south) summit occur, Mount Bryan, 3000 feet high. From these parts it extends nearly due north, with a small declination to

*(From a historical text, discussing the geographical and natural features of the Southern Ocean and related areas, with specific mention of the Iliad and the Odyssey translations by a noted poet.)*

---
In its natural state it resembles a park, the single trees standing at considerable distances from each other.

The capital of the state is Adelaide. It is situated on the southern border of the Torrens, a river which rises in the hills about six miles east of the town. It can be called a river only in the rainy season, for in dry weather it is all but dry, and flows only during these periods of high velocity. In the dry season it consists of a number of expansions like small lakes, which are very deep and of considerable length, but rarely more than thirty or forty feet wide. These ponds are connected with one another by shallow places, in which the water is hardly a foot wide and an inch deep. At these places hardly a current is perceptible in the dry season. The Torrens in that season does not reach the sea, but instead it is in what is called a swamplike depression, overgrown with reeds, which is separated from the shores by the sandy down. When the river is full, the surpluses of water find their way to the sea by running from the Reid-Bed to the Creek. The Creek is an inlet, branching off from the Gulf of St. Vincent about twelve miles to the north-west of Adelaide. It runs about four miles eastward and then twelve miles southward, terminating not far from the Reid-Bed. Though there is a bank at the entrance of the creek, with only fourteen or fifteen feet of water over it, vessels of five hundred tons burden can sail up to Port Adelaide, which is only five miles from the town, and has a good landing-place. The coastal line in the reefs of Adelaide is brackish, that of the Torrens river is used for all purposes, and is even transported to Port Adelaide by rail.

The Murray is the largest river in Australia, and its remotest tributaries rise in the mountains which are not far from the eastern shores of that continent. [Australia, P., p. 121; Walms, New Beza, P. C., p. 38 and 44.] It enters South Australia near 89° S. lat., and flows for about eighty miles west, when it suddenly turns to the south, and runs in that direction to the sea; before entering into the sea it expands into a large lake, called Lake Victoria. This navigable river runs in a bottom inclined by higher ground, from twenty to forty feet above the bottom. The bottom is about four miles wide. As the river does not occupy the centre of the bottom, but inclines to either side according to its windings, the flats on its sides are of greater or less extent, according to the distance of the river from the base of the higher grounds. The bottom is level, and almost everywhere overgrown with high reeds. The soil is of the richest kind, being formed by an accumulation of vegetable matter, and as black as ebony; but as the destruction of the reeds would require much labour, no trial has hitherto been made to bring it under cultivation. Lake Victoria is about sixty miles long, and about eight miles wide in the widest part. It has no great depth, and is united to Encounter Bay by three channels of little depth; the shortest of these channels is four miles long. From the sources of the Murray, north of Victoria, boatmen have travelled, in which after two miles gradually expands into another lake of smaller dimensions, called Lake Albert. This lake is not connected with the sea, but separated from it by a sandy neck of land and the Gulf of St. Vincent.

The higher country between the Murray River and the hilly tract which forms the watershed between it and the Gulf of St. Vincent is rather hilly near the bend of the river, and overgrown with light woods; it appears to be adapted for sheep-walks. Nearer the sea the soil is sandy, and appears to possess only a small degree of fertility; but in the vicinity of Lake Victoria it is beautifully studded with cyrpress. The country east of the Murray is of a more barren description. The soil contains a much greater portion of sand, and it is covered in its natural state with low brush; large trees occur only at some spots. In some places it is covered with scrub, and in others it is sandy, with no indication of vegetation or water. The last-mentioned observation applies especially to the country which begins on the banks of the river, and extends to the eastern boundary of the colony.

The interior of the country, which, south of the parallel of Lake Victoria, extends from the sea to 141° E. long., is a desert; its surface being formed by a succession of low ridges or elevations, and shallow depressions in which only shrubbery grows. At the sea-mouth of the Murray begins a narrow arm of the sea, which extends along the shores and parallels to them over an extent of more than a hundred miles. In the vicinity of Lake Albert the open sea by a narrow strip of land covered with sand-
downs of moderate elevation. At the back of the northern half of the island there is a belt of high hills overgrown with casuarina, and between them numerous plains of moderate extent with a good soil; fresh water is found at a moderate depth under ground, rarely exceeding six feet. The rain ends in June; on the northern side of the island, the north-western side of the southern half of the Coroong there is a succession of salt swamps and low shrubby hills. A low range, called the Wombat Range, runs for twenty miles parallel to the coast. One side of the Coroong is of about three miles. Behind three miles of it is an extensive fresh-water swamp, several miles across, which appears to be subject to annual inundations. The soil of this swamp is similar to that of the flats of the river Murray. Fresh water is found in the swamp many small sandhills, well wooded and grazed.

The Coroong terminates near 36° 30' S. lat., but in the line of its continuation are a number of lakes, which are separated from the sea not by sand-dunes, but by grassy flats. At the back of the lakes are several grassy plains with a good soil, and wooded hills. South of Cape Bernouilli (near 37° S. lat.) the country improves. It consists of several ranges of wooded hills, generally running parallel to the shores, which are separated from each other by low level grounds, a great portion of which is subject to inundation; but the soil is excellent, and in many places these flats are dry and available for pasturage or culturization.

The south-eastern portion of South Australia will certainly become a very valuable country. A line drawn from Rivoli Bay nearly due east to the boundary-line divides it from the desert and from the north. Nearly the whole of the low ranges of wooded hills alternate with grassy plains and a few swamps. In approaching the higher country plains occur, which consist of caroong, covered with luxuriant foresta, consisting of trees of great size, blackwood, gum, stringy bark, and mahogany. They extend to the foot of Burr Range, a mountain-tract divided into several ridges, which cover a great extent of surface, and are pretty well wooded. The highest point of this range rises to about 1000 feet above the sea. Between this range and the isolated mountains called Mount Gambier and Mount Schank lies a well inclosed tract with large timber-trees, and an excellent soil. The two last-mentioned summits are of volcanic origin. Three distinct craters are visible on Mount Schank, which is between 900 and 900 feet above the sea. Mount Gambier is higher, and has also a crater on its summit. The soil of this region is of the richest description, being mostly a black brown loam, and the vegetation luxuriant. The value of this country for settlers is still increased by having a good and safe harbour in Rivoli Bay.

Kangaroo Island, which lies before the entrance of the Gulf of St. Vincent, is about 80 miles long from east to west, and on an average about 20 miles wide, which gives an area of 1600 miles. It rises steeply from the sea, and does not attain a great elevation, the interior being occupied by extensive plains. Close to the shore, within a quarter to half a mile from the sea, it is covered with a thick forest, but as you ascend the height is passed, and the country presents itself, which is covered with grass, and there are often hundreds of acres without a tree. In these plains are numerous ponds, and, near the shore, lagoons which are generally filled with fresh water, but some are salt. On the shores of Nepean Bay is a salt-lagoon, on the banks of which large masses of crystallized salt are found. It would seem that nearly the whole of the island is available for agriculture or pastureage. On its north-eastern shore is Nepean Bay, where vessels may ride in perfect security during the western gales.

It is true that by far the greater part of the territory of South Australia will never produce any food for man or animals, but the country is well suited for several very good tracts of land. It is probable that one-twentieth of the whole will either be brought under the plough or used as pasture-ground for sheep and cattle. This would appear to be a large country, the extent of which has not been ascertained, but it is probable that there are about 50,000 square miles.

As this country has only lately been settled, we are but imperfectly acquainted with its climate. No series of meteorological observations has reached us, and we must necessarily content ourselves with some general observations. The seasons are divided into dry and wet. The dry season begins at the end of August and continues to the end of March. In December and January, July, and August, the heat is very great, and the ground so arid, that the least breeze raises clouds of dust. During the wet season, from the end of March to August, it rains frequently and sometimes very heavily. The long droughts, with which New South Wales and South Australia are frequently visited, are less frequent in South Australia. It appears that the rain diminishes greatly as we proceed inland, and it is probable that it ceases entirely before it reaches the northern boundary-line of the colony. During the dry season the rains are exceedingly frequent in hard gales. In the dry season northern and north-eastern winds prevail. Frost has never been experienced, nor by any means of snow.

During the cold season a great number of whales visit the coasts of the colony, and are chased by British, American, and French vessels. The black whale is most frequent, but the sperm-whale also occurs. The native animals are the kangaroo, wallabbi, a sort of small wallaby, the genus, the opossum, and the dingo, or Australian dog. Birds are numerous, and distinguished by their beauty. The emu, several kinds of parrots, of cockatoos, partridges, and quails are common. The most common sea-fowl are pelicans, black swans, wild ducks, divers, waders, coromants, and Cape-pigeons (Procellaria Capensia). Several kinds of fish are taken in the sea, as salmon, snappers, porpises, and large and small sharks. There are several kinds of snakes and lizards; among the latter the iguana, which is eaten; among shell-fish, oysters and periwinkles are mentioned as plentiful.

The colonists have imported horses from Tasmania and New South Wales, and ponies from the island of Timor in the Indian Archipelago; cattle and sheep from the Cape, Tasmania, and New South Wales; and hogs from New Zealand. Fowls are common, both the common species and the larger one from the South Sea Islands, and both the small and large breeds of the bull-dog and greyhound, and used for chasing the emus and kangaroos; such a dog is often sold for 25 or 30 pounds sterling.

The woods of South Australia contain many large trees, but the timber is not much valued; and this article is imported from New South Wales and New Zealand. All kinds of grain have been introduced, and appear to succeed pretty well; maize grows well, and also potatoes; melons, water-melons, pumpkins, and cucumbers attain an uncommon size, and also cauliflowers. Onions are cultivated to a great extent in Kangaroo Island. Our fruit-trees do not appear to grow well, except the peach, and there is a small kind of lemon; for apples, pears, &c. the climate appears to be too hot and dry. The vine has not succeeded, but probably it will. No edible fruit is indigenous, except some berries, which are eaten by the natives.

It appears that South Australia is rich in minerals. Iron-ore has been found in many places, especially in the deserts; but it will probably never be turned to account, for want of fuel in these parts. Copper-ore has also been found at some places in the vicinity of the settlements; and a quantity has already been shipped for England. It is stated that this ore contains 14 per cent. of copper. There are numerous deposits of salt in the deserts; and there is also a salt-lagoon on Kangaroo Island, and others on the coast of the colony which lies to the east of Lake Victoria.

The natives of South Australia, like those of New South Wales, belong to that race which is called Negro Australian; but it appears they have not yet attained an equal degree of civilization with the native population of the eastern coast of Australia. This however may partly be the effect of the shorter duration of their communication with Europeans. When their hunger is satisfied, nothing can induce them to work, but when pressed by want of food they are ready to do any kind of labour for the colonist, especially carrying water or wood. It seems therefore that by able management they perhaps could be accustomed to some regular work, especially if there were a few flocks of domestic sheep. Though it appears certain that all the natives of the southern and eastern coast of Australia speak the same language, a marked difference exists in the dialects spoken in different parts of the same country. The language spoken by the natives of South Australia; one is spoken by the few isolated families which live in the eastern districts west of 136° E. long.; another by the inhabitants of the vicinity of Adelaide; and the third by those who wander about on the banks of the Murray River. A native of King George's Sound, in West Australia, who accompanied Mr. Eyre in his journey to our June and July, speaks the language spoken by the families of the Australian Blight.

The settlement of Adelaide was founded in 1836; but six or nine months previously some families had settled on
Nepean Bay, on Kangaroo Island, at a place called Kingscote. At the close of the voyage it was very great; and in 1840 the number of the white population was estimated at 15,000. In 1838 the colonies of Port Phillip and New Zealand were founded; which offered greater advantages for the settlement of Spanish emigrants than to those countries; and since 1840, very few have gone to South Australia. The white population at present probably does not exceed 20,000 individuals. The greater number of emigrants was not made till the settlement of the vicinity of Adelaide. A settlement exists at a place a little above the influx of Murray River into Lake Victoria, called Wellington. The settlement at Kingscote has been mentioned above.

There is also another on Spencer's Gulf, at Port Lincoln.

SOUTH SEA BUBBLE. The original conception and establishment of the South Sea Company was a project of Queen Anne's minister, Harley (afterwards Earl of Oxford), soon after the greatest weight in the House of Commons was removed in favor of the Government. The object of this company was to provide the means for paying interest at 6 per cent. upon, and eventually discharging, certain arrears which had accumulated upon the navy, victualling, transport, ordnance, and other departments, amounting, together with a new loan of 500,000l., to 9,471,325l. in all. For this purpose the crown was authorized by stat. 9 Ann. c. 21, entitled 'An Act for making good deficiencies and satisfying the public debts, and for creating a corporation to carry on a trade to the South Seas, and for the encouragement of the Fishery,' &c., to incorporate all the persons interested in any of the bills, tickets, debentures, or certificates, or other public debts, deficiencies, or sums of money, intended to be provided for by the act, into a company; whose stock should consist of the said debts, or claims upon the public; and in which should be vested, from the 1st of August, 1711, for ever, the sole trade and traffic into, unto, and from all the kingdoms, lands, countries, territories, islands, cities, towns, ports, havens, creeks, and places of America, on the east side thereof, from the river of Aranoco to the southernmost part of the Terra del Fuego; and, on the west side thereof, from the said southernmost part of the said Terra del Fuego, through the South Seas, to the northernmost part of America; and into, unto, and from all countries, islands, and places, within the dominion of Spain, in the crown of Spain, or which shall hereafter be found out or discovered within the said limits, not exceeding 300 leagues from the coast of America, between the southernmost part of the Terra del Fuego, and the northernmost part of America, on the west side thereof; except the kingdom of Brazil, and such other places on the said east side of America as are now in the actual possession of the crown of Portugal, and the country of Surinam in the possession of the States-General of the United Provinces. On the 8th of September, 1711, a charter was granted establishing the company by the name of 'The Governor and Company of the Merchants of Great Britain trading to the South Seas and other parts of America.' The establishment of the South Sea Company went for a time to the honor of the House of Commons. It was anticipated that it would pour a continued stream of gold and silver into England from the mines of Mexico and Peru. In point of fact however, the trade which the company engaged in was altogether a failure. 'By the peace of Utrecht,' says Coxe (Memoirs of Sir Robert Walpole, i. 127), 'Spain and the Indies being confirmed to Philip V., that monarch was too jealous to admit the South Sea Company. Many of them were speculators in the advantageous commerce which Oxford had held forth; the Company obtained only the Asiento contract (P. C., ii. 508), or the privilege of supplying the Spanish colonies of America with provisions. There was no such thing as a demand for Spanish America an annual ship, limited both as to tonnage and value of cargo, of the profits of which the King of Spain reserved one fourth, and five per cent. on the other three fourths. The disappointment was attempted to be counteracted by the declaration made by Oxford, that Spain had permitted two ships, in addition to the annual ship, to carry merchandise during the first year to the northern coasts of Spanish America; and the nomination of the several ports where the Company had leave to trade and settle factories. But the grand benefits of this commerce were never realized. The first voyage of the annual ship was made in the following year, and the trade was suppressed by the rupture with Spain. Their effects, factories, and servants were seized and detained, notwithstanding the agreement in the Asiento which allowed, in case of a rupture, eighteen months for the removal of their effects.'

This was the state of its affairs when, in the year 1719 or beginning of 1720, the ministry of Sunderland and Stanhope secretly entered into arrangements with the Company for having the whole amount of the National Debt, amounting to above 30,000,000l., transferred into its stock upon certain conditions. In conformity with what had been agreed upon between the parties, the Directors of the Company, on the 29th of January, 1720, sent in their proposal to the House of Commons, engaging to pay 3,500,000l. for the liberty of increasing their capital by being thus constituted the sole national stock. The mistake of the ministry was disappointed in their expectation of the scheme being at once assented to by the House. It was suggested that other proposals should be invited; and Walpole, who had already committed himself, having support from the Commons, it was agreed after some debate that the matter should be thrown open to competition. In consequence, on the 27th of February they sent in a second proposal in which they offered to pay 3,750,000l. Upon this a General Court of the members of the South Sea Company, the Directors were instructed to obtain the preference cost what it would; and on the 1st of February they sent in a second proposal to the House of Commons offering with paying 7,422,400l. 'A bill for a second proposal on the same day, which was supported by Walpole; but on the representations of Aslieble, the chancellor of the exchequer, it was resolved that the proposal of the South Sea Company should be accepted.' A bill effect was forthwith brought in, which, after several debates, passed the Commons on the 2nd of April, by a majority of 172 to 65, and the third reading of which was carried on the 7th in the Lords without a division. The same day it received the royal assent, and became the statute 6 Geo. 1. c. 4.

The imaginary advantages accruing to the Company from this arrangement instantly produced a great rise in the market value of its stock. The profits of the scheme were enumerated by Coxe as being expected to arise from—'1. The exclusive advantages of the trade, which, although precarious, and depending on a peace with Spain, were stated at no less than 30,000,000l. a year; 2. The monopoly of the trade, or monopoly of the consumption, which was to be proportioned to the augmentation of their stock; 3. The difference of receiving five per cent. for the money expended in purchasing the public stock, as against the usual interest of but four per cent.; 4. The great addition to their wealth from the constant rise in the price of the stock in consequence of the artificial use made to enhance its value; on which the whole success of the scheme depended.' 'The promoters of the scheme,' adds Coxe, 'highly exaggerated the profits; rumours were at the same time spread that the Company, by monopolizing the fund of the whole national debt, would reduce Government to the necessity of applying to them for loans, which would be advanced on their own terms; and it was even insinuated that the proprietors would obtain, by the weight of their wealth, a seat in the cabinet, or a place in the ministry.' The consequence was that the price of the stock, which at Christmas, 1719, stood at 126, had risen by the 14th of April to 326, and by the end of August to above 600. Meanwhile it had been started by the rage and fury of speculation which this rapid ascent of the Company's stock had excited; and all or almost all of these also, incredibly visionary and absurd as it was, contributed with temporary success. In Anderson's History of Commerce a list of nearly two hundred of these minor bubbles is given. About Midsummer it was calculated that the value of the stock of all the different companies amounted to 100 millions, and it exceeded five hundred millions sterling. Now however the South Sea Company, envied in the midst of its own prosperity...
of that of its rivals, procured writs of scire facias to be directed against certain of the other companies. The effect was instantaneous and universal. Alarmed by the apprehension of prosecutions by the law officers of the crown, the subscribers to the ‘Ships for India’ bond, especially those owning a larger proportion of the shares for whatever they would bring, more eagerly than they had done to purchase them; the panic quickly spread through the whole extent of the share-market: the proprietors of the vessels were hurried to the exchanges, and legally incorporated companies, subsequently, by the general aspect of things around them, began to perceive that their stock too must have its point of highest elevation, from which it would as inevitably descend as would after a certain time the tide, from the mouth of a stream, and under the impression South Sea stock itself soon began to tumble down. By the 32nd of August it had fallen to 820; by the 30th it was at 780; by the 8th of September at 680; by the 20th at 410; by the 25th at 176. The bubble had burst.

It would require a great deal of space to tell the rest of the story of this remarkable financial inflation and fever. A searching parliamentary investigation into the proceedings of the directors of the company followed in the next session, which produced many most scandalous disclosures, some of them affecting the most eminent persons in the country. The directors were all mulcted of the greater part of their fortunes; Atkyns, the chancellor of the exchequer, was expelled from the House of Commons; Crags, the secretary of state, would probably have shared the same fate if he had not died of small-pox in the course of the proceedings, his son being called to the bar on the 28th of December; Somerset House was of course attacked by the disease shouldering up the island was with difficulty saved by the influence of Walpole; Stanhope, who was not supposed to be implicated in the fraud and scandal, was first游戏角色 blood vesSEL was breaking upon him, a subject in the House of Lords, and expired the next day. Not only the royal mistresses, but the Prince of Wales, and even the king himself, were believed upon strong grounds to have profited largely by stock which they were favourably placed for selling at the most advantageous moment, and all or the greater part of which they had obtained without purchase.

The storm thus raised was weathered and slaved, and public credit restored, principally by the great financial talent of Walpole, who assumed the direction of affairs as first lord of the treasury and chancellor of the exchequer in February, 1721, and kept his post at the head of the government for the next twenty-one years. Even the affairs of the South Sea Company were by the measures which he adopted restored to some degree of real prosperity for a time; but its commercial operations never became of any consequence; and the members became at last mere government annuitants, till, all their claims having been satisfied, the company was finally dissolved only a few years ago.

It has been forgotten that the South Sea Bubble in England was coincident in point of time with the later stage of the famous Mississippi scheme of Law in France; but what real connection there may have been, if any, between the one and the other is a matter of question.

(Prestwich’s Historical State of the South Sea Company; Anderson’s Chronological Deduction of Commerce; Macpherson’s Annuals of Commerce; Crook’s History of British Commerce; Cusack’s Memoirs of Walpole; Malcolm’s History of London; Parliamentary History; Statutes at Law.)

SOUTH, ROBERT, LL.D. The little that there is to be told of the life of Southey beyond the account of his literary performances may most conveniently be given by itself in the first instance. He was one of several sons of a linen-draper in Wain-street, Bristol, where he was born—his name is found in the list of August 1774, but, according to the inscription on his tombstone, on the 4th of October in that year. His first teachers were, a Baptist clergyman named Foot, said to have been a man of no ordinary ability, to whose school he was sent when he was six years old; then a Mr. Flower, at Corston, near Newton St. Loe; then a Mr. William Williams, a Welshman (something dropped into his mind by which he may have been suggested the subject of his ‘Mabinogion’). At last, in 1788, he was placed at Westminster school, the expense of his education from this time, it is intimated, being borne by Mr. Hill, a brother of his mother, who was an officer second in command at the Cape of Good Hope. His father, we suppose, was now dead. In 1792, leaving a distinguished reputation at Westminster, where however he had incurred censure for taking part in a rebellion against the head master, Dr. Vincient, in 1790, he was sent to Baliol College, Oxford, his uncle’s intention being that he should enter the church. But it was almost unavoidable that his enthusiastic temperament should precipitate him into the so-called liberal opinions both in religion and politics which the French Revolution had inspired, and which he propagated both in France and in this country; he went to the extreme of free-thinking on both subjects; and in 1794 he left Oxford. He and a fellow-townswoman, a young Quaker named Mrs. Lovell, who was also at Oxford, and in 1794 the strength of this aversion for the Roman Church prompted them to leave England, and they became friends and associates of Coleridge. They lived for a time in Swiss places, with their joint fortune—amounting to about £2000, in money, besides a valuable library, which was afterwards disposed of by auction in London.

Southey’s publications are very numerous. The following list of those of them that appeared separately is probably not quite complete, although we have taken great pains to make it so; but, at this, we believe, much the fullest that has been drawn up:

In 1794, Poems, in conjunction with his friend Lovell (as stated above on the authority of the Gentleman’s Magazine), under the title ‘Poems’ (12mo, 2 vol. 6vo).

In 1795 (according to Lowndes’s Bibliographer’s Manual), Poems, containing the Retrospect, Odes, Elegies, Sonnets, &c., by Robert Lovell, and Robert Southey, of Baliol College, Oxford, 2 vol. 6vo.
In 1796, Joan of Arc, an Epie Poem, 4to.
In 1797, Poems, 5vo.—Letters written during a short residence in Spain and Portugal, 12mo.
In 1799 and 1800, The Annual Anthology (a miscellaneous collection of poetry, of which he was the editor and principal writer), 2 vols. 8vo.
In 1800, The Thalassa the Destroyer, a Metrical Romance, 2 vols. 12mo.
In 1803, Amadis de Gaul (a prose translation from the Spanish version by Garcia Ordoñez de Montalvo of that romantic novel, originally written in Portuguese by Vasco de Lobeira), 4 vols. 12mo.—The works of Thomas Chatterton (in conjunction with Mr. Amos Cottle, the Life, originally printed in the second edition of the British Antiquties, being by Dr. G. Gregory), 3 vols. 8vo.
In 1804, Metrical Tales, and other Poems, 8vo.
In 1805, Madoc, a Poem, in Two Parts, 4to.
In 1808, The Chronicle of the Cid, Rodrigo Diaz de Bivar, from the Spanish, 8vo.
In 1810, The Curse of Kehama, a poem, 4to.—The History of Brazil, vol. i. 4to.
In 1812, Omnia, 2 vols. 8vo.
In 1815, Life of Lavoisier, 8vo.
In 1814, Carmen Triumphale for the commencement of the year 1814, 4to.—Ode to the Prince Regent, the Emperor of Russia, and the King of Prussia, 4to.—Roderick, the Last of the Gallaerts (a poem), 4to.
In 1816, The Lay of the Laureate; Carmen Nuphila (a poem on the marriage of the Princess Charlotte), 12mo.—A Poet's Pilgrimage to Waterloo, 8vo.
In 1817, Wat Tyler, a Dramatic Poem (written, in a vein of ultra-Jacobinism, in 1784, and now surreptitiously published), 12mo.—A Letter to William Smith, Esq., M.P. (on the subject of the preceding publication), 8vo.—Morte Arthur (a reprint of Sir Thomas Malory's prose romance), with Introduction and Notes, 3 vols. 4to.—History of Brazil, vol. ii. 4to.
In 1819, History of Brazil, vol. iii. 4to.
In 1820, Life of John Wesley, 2 vols. 8vo.
In 1821, A Vision of Judgment (a poem in English hexameters), 4to.—The Expedition of Ozma and the Crimes of Aguirre (partially printed in 1821, in the Second Part of the 12th Volume of the Edinburgh Annual Register, for 1810), 12mo.
In 1822, Letter to the Editor of the Courier Newspaper, dated Keewick, January 5th, and published in the Courier of January 17th, 1821 (a poem politique written by Lord Byron to the tragedy of the Two Pencans).—Remains of Henry Kirke White, vol. iii. 8vo.—History of the Peninsular War, vol. i. 4to. (an expansion of what had been originally published in the 12th and 13th Volumes of the Edinburgh Annual Register, 1810, &c.)
In 1824, The Book of the Church, 2 vols. 8vo.
In 1825, A Tale of Paraguay (a poem), 12mo.
In 1826, Vindiciae Ecclesiae Anglicanae, &c., 8vo.
In 1827, History of the Peninsular War, vol. ii. 4to.
In 1829, Sir Thomas More; or, Colloquies on the Progresses and Prospects of Society, &c., 2 vols. 8vo.—All for Love, or The Sinner well Saved; and The Pilgrim to Copamottela, or A Legend of a Cock and a Hen, 12mo.
In 1832, Essays, Moral and Political, 2 vols. 8vo.—Selections from Southey, Prose, 12mo.—History of the Peninsular War, vol. iii. 4to.
In 1833, General History of England, vol. i. 12mo. (in Lardner's Cabinet Cyclopaedia); completed in 5 vols. in 1840.
In 1834, Dr. Watts's Poems, with a Life of the Author (Cattermole's Sacred Classics), 12mo.—The Doctor (anonymous, and never acknowledged, but believed to be Southey), vol. i. and ii. 8vo.

In 1837, The Poetical Works of Robert Southey, collected by himself, 10 vols. 12mo.—The Doctor, vol. iv. and v. 8vo.—Life of the 1st Earl of Selkirk, post 4to. (according to Lowndes, who however gives no date).

To these works, making in all above a hundred volumes of various sizes, are to be added numerous papers upon history, biography, and miscellaneous literature, published in the Quarterly Review, to which he was a constant contributor from its establishment in 1809, till head and hand would work no longer. He also wrote for some years the historical portion of the Edinburgh Annual Register, and contributed other matter to that work, which began to be published in 1810, and was discontinued in 1824. He was besides one of the most regular and voluminous of letter-writers; and large collections of his letters are understood to be in existence, which it is to be hoped will, ere long, be given to the world. Some have already appeared in Robberia's Memoirs of the Life and Writings of William Taylor, of Norwich, 2 vols. 8vo, 1842.

As a poet, Southey cannot be placed in the first rank even of the poets of his own time. Wordsworth and Coleridge, Shelley and Keats, Byron and Scott, Moore and Crabbe and Campbell, whatever differences of opinion there may be as to their relative merits or their positions in reference to one another, will be generally admitted to have each and all shone more brightly as a mere director which was wanting in him. The light which was original in him shone upon one other, shone, even when it shone the strongest, to be only reflected light in him. In mere fertility he was equal to any of them. But his mind, although it was certainly not an inventive or constructive mind, returned much mind to the seed deposited in it, and communicated to it comparatively little of any new nature or quality. His imagination might even be said to be both apulent and gorgeous; still there was wanting the true spirit of life, that which distinguishes a real thing from a painted show. No natural human voice coming from the poet himself animated his verse; but rather an artificial sound, as from a flute or an organ. Such poetry may be both beautiful and majestic; but it fails permanently to interest, and will not live. For there is nothing so alien from and so fatal to poetry as any admixture of the mechanical. It acts like a dead substance imbedded in a living body. Witness such an instance as that of Darwin. There is much rhetorical splendour however in parts of Southey's poetry; especially in his 'Curse of Kehama,' and in his 'Roderick.' And some of his ballads and other shorter pieces, flowing on as they do in the easiest and purest English, are very happy.

In his prose writings the great merits of his style show to all advantage. It is essentially a prose style, and one turned to poetry by his high order, by some of the very qualities that constitute its characteristic excellence. Its facility and fluency, running into some degree of diffuseness; its limpid perspicuity; its equbility and smoothness; its power (as I say) of passion, the rapidity, the boldness, the novel combinations of poetry. Both in its merits and in its defects Southey's style may be compared to glass, which perfectly transmits the light, but refuses it not of the rise to any splendour of elegance; it has little or no brilliancy of any kind; but whether for narrative, for exposition, or for animated argumentation, it was perhaps the most effective English style of the time. It combines in a remarkable degree a somewhat lofty dignity with ease and idiomatic vigour, and is equally pliable to the expression of sprightly and playful as of severe and dignified sentiment. He certainly was not nearly so great a thinker as he was a writer. He had no subtlety of intellect, and he took rather a passionate than a reasoning view of any subject that greatly interested him. Much of his political and economical speculation is now printed originally written as another rather wrong-headed, even by the most ardent of his admirers. But there can be no question that he was thoroughly honest and in earnest in whatever opinions he at any time professed. He was, by the universal testimony of those who knew him best, a man of sincere, generous, high-minded nature, and in all the relations of private life a man worthy of the highest estimation.

Memoir in Gent. Mag. for June, 1845; Dictionary of Literary Authors, vol. ii.; Cattermole's Classical Literature; Literary Gazette; Athenaeum; and the works mentioned in the article.)

[SOWENS, EDWARD, P. C. S.]

SPACE, POWER OF PENETRATING. [TELESCOPES, P. C. p. 163]
SPALDING, SAMUEL, was born in London on the 30th of May, 1897. He furnished an example of success above the general average, of usefulness and usefulness, in the absence of any remarkable ability or aptness for its attainment. According to the testimony of his friends, he was only by means of great labour that he could perform his daily tasks with ease and without strain, and the steady progress which he made must have been much more at this early period of his life from a sense of duty, the effect of moral and religious training, enabled him to acquit himself with great respectability; and the moderate intelligence that he possessed appears to have done much towards forming those habits of unremitting application which constituted one of the strongest features of his intellectual character. At a suitable age he went to a public school, but had soon become too deeply interested in the study of theology to allow him to entertain the idea of spending his life in a secular profession. He now examined the evidences of Christianity was most astounded, and the work of Dr. Chalmers on this subject, together with the splendid discourses of the same writer on the relation of revelation to the discoveries of modern astronomy, inspired his mind with such elevated views of the grandeur of Christianity and the extensive benevolence of its design, that he resolved to devote himself to the pastoral office in the religious connexion to which he belonged, that of the Church of England. He frequently applied himself to study with fresh ardour, though he had to contend with a naturally feeble constitution, in which there is little doubt that the seeds of organic disease early existed. The contemplations of his mother's relations, was benevolence. In him it extended from the worm, which he would stoop to pick up lest it should be trodden on, to the highest order of beings. Whatever was capable of suffering or enjoyment excited his sympathy.

With a view to promote his object of qualifying himself for the ministry, Spalding devoted his time, for two years, to the study of the Greek and Latin languages, in private; and afterwards entered as a student of Christ's College, at Cambridge, where he made himself an exact Greek scholar. During his academical course here he obtained, in addition to high certificates of honour in other classes, five first prizes in the classes of Hebrew, French, Natural Philosophy, and the Philosophy of the Mind and Logic. Of the last subject his pursuit was ardent, his diligence and ability, as manifested in his essays and examinations, being such as to mark him out as a student of unusual merit. In the year 1839, symptoms of incipient pulmonary disease induced him to try the effect of a warmer climate, and he spent the winter in the South of France. On his return he underwent the examination for the M.A. degree in the University of London, in May, 1840. In the Transactions of the University, his name is mentioned with honour for his examinations in Animal and Vegetable Physiology, and in Law, Greek and Greek original and the History of the Holy Scriptures. He is also recorded as having passed a distinguished examination in Logic, the Philosophy of the Mind, and Moral Philosophy. In the latter he was so successful he was allowed by the examiners to write on some of these subjects; and this remarkable encouragement encouraged him to compose his work, entitled ' The Philosophy of Christian Morals.' In the autumn of 1840, Spalding went to Italy, where he remained nearly two years. It was during this period that the above-mentioned work was written, the subject of which however had occupied his mind for many years. On his return to England, in 1843, he published with great success the Treatise, but was prevented by the progress of his disease; and as a last resource he tried a sea-voyage, and went to the Cape of Good Hope, where he died on the 14th of January, 1843, about three weeks after his arrival. His work was published the same year, by his friends, in one volume, octavo. We have no space for any criticism of Spalding's theory of morals: we must restrict ourselves to a bare summary of his principal doctrines. They are as follows:—

1. Moral obligation is, first, virtue itself; and, secondly, the mode in which virtue ought to be displayed in the outward conduct. The great rule of action is, either to do to others what we expect others to do to ourselves.

2. The notion of moral obligation is an immediate consequence of the testimony of our moral emotions. The great object of moral approbation is the principle of benevolence; each of our actions, and each of our states of mind, is directed or cultivated in itself, to the direct or indirect advancement of this end. Thus, for example, we can have the notion of virtue or of vice, and by its reduction of all the forms of virtue to the one principle of benevolence. Without pronouncing either one way or the other on the merits of this theory, we will only observe that it possesses considerable originality, and abounds with passages of genuine power and beauty; and that it is characterised throughout by an elevation of thought and sentiment which distinguishes it even among books on ethical subjects. The author writes with the glowing warmth of one whose heart is in his work, sometimes with an intense ardour of feeling. The book is therefore of a popular cast, though it often discusses principles ably and profoundly. It exhibits also in a striking manner the real harmony subsisting between the Christian precepts and the genuine dictates of the moral faculty, notwithstanding apparent or supposed discordances. It exhibits a strong instinctive and party feeling, and exhibits very advantageously the benevolence which was a distinguishing characteristic of the author's mind.

Spathodesa, a genus of grasses belonging to the tribe Chlorideae. The flowers are paniculate, the glumes unequal, the upper long and acuminate; the paleae unequal, the outer boat-shaped, compressed, retuse; the styles elongated, united half-way up; the stigmas biform, protruding at the summit of the flower. There are two British species, the stricta and S. alterniflora. The former grows in muddy salt-marshes, the latter has been found only on the mud-flats of the river Irthing at Southhampton.

Spathodea (from spath, a spathe, in reference to the form of the calyx), a genus of plants belonging to the natural order Bignoniaceae. The calyx is spathaceous, cleft and toothed or entire on the other side. The corolla is funnel-shaped, with a 5-lobed rather unequal limb. The 4 stamens are divided into 2 long and 2 short, with the addition of a fifth sterile filament. The capsule silique-form, falcate, falsely 4-celled, and corky. The seeds are furnished with membranous wings. The species are erect shrubs or trees, rarely climbing shrubs. The flowers somewhat panicked, orange-coloured, yellow, or purple.

S. Rhodea has domed, lanceolate leaves, roundish downy leaflets, terminal erect racemes, and a much-curved slender corolla. The shoots are covered with a whitish down. The racemes the length of the leaves. The flowers white and purple. The fruit about a foot long, pendulous, twisted in various forms.

S. Rosbushii has its leaves three in a whorl or scattered impari-pinnate. The leaflets from 4 to 6, in pairs, serrated and smooth, with a roundish base. The corolla is terminal, purple and many-flowered. The fruit narrow and 4-celled. The calyx generally 2-parted, with the upper lip 2-cleft and downy. It is native of the Circassia. The branches are very spreading. The back grey, with a few scarious spots. The flowers large, rose-coloured, and delightfully fragrant. The limb of the corolla nearly equal, and elegantly waved at the edges. The species is remarkable on account of its scarlet leaves. The wood is employed for many purposes by the natives.

S. longiflora is an arborescent plant, and has large spreading terminal panicles, a bilabiate corolla, long pendulous slender sub-cylindrical follicles, with sharp edges and variously curved. The flowers are large, yellow, and very fragrant. The follicles very long. The wood of this tree is high-coloured, hard, durable, and much used for musical instruments and the like, the latter about the coasts of Coromandel and Malabar, where it is plentiful.

The species are splendid plants when in blossom. A mixture of the two is the reveller from best, and cuttings will strike readily in heat under a glass.

(Don, Garden's Dictionary.)

Spatularia, a genus of fishes of the Sturgeone tribe, remarkable for its mouth, which is only revealed by a prolonged and leaf-like form. The paddle-fish of the Mississippi is the type.
The difference between the specific heats at different temperatures is ascribed to the dilatations which the substances experience by an increase of heat; every change in the constitution of a substance is accompanied by a change of specific heat; a solid body, for example, has a smaller specific heat than the same mass in a liquid state. Thus the specific heat of water being unity, that of ice is 0.9.

With respect to liquids, Lavoisier and La Place have given a table of their specific heats, of which the following is an extract:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Specific Heat</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mercury</td>
<td>0.99</td>
</tr>
<tr>
<td>Sulphuric acid</td>
<td>3.84596</td>
</tr>
<tr>
<td>A mixture of sulphuric acid and water</td>
<td>0.603162</td>
</tr>
<tr>
<td>Nitric acid</td>
<td>0.61391</td>
</tr>
<tr>
<td>Water</td>
<td>1.0</td>
</tr>
</tbody>
</table>

The specific heats of gases are still subject to much uncertainty, though many attempts have been made by eminent physicists. During the siege of Hamburg, in the winter of 1813-14, MM. Delarochelle and Bérard for this purpose was to transmit through the calorimeter a constant current of gas in a serpentine tube, the gas having been heated to the temperature of the sun's rays. The thermometer of bull's horn, which is easily visible to the eye, being placed in the instrument; and the gas, passing with its excess of sensible heat above that of the surrounding water, issued from the tube at the temperature of the water, the temperature of the gas at the exit being determined by means of thermometers. The following table contains the results of some of their experiments on different gases, the weights of the quantities of gas being equal and the specific heat of water being unity:

<table>
<thead>
<tr>
<th>Gas</th>
<th>Specific Heat</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbonic acid gas</td>
<td>0.9210</td>
</tr>
<tr>
<td>Oxygen gas</td>
<td>0.2361</td>
</tr>
<tr>
<td>Atmospheric air</td>
<td>0.0659</td>
</tr>
<tr>
<td>Nitrogen gas</td>
<td>0.0747</td>
</tr>
<tr>
<td>Olefiant gas</td>
<td>0.4207</td>
</tr>
<tr>
<td>Aqueous vapour</td>
<td>0.8470</td>
</tr>
<tr>
<td>Hydrogen gas</td>
<td>3.9386</td>
</tr>
</tbody>
</table>

The specific heats of volumes of the same gas, having equal weights, are found to vary with the density and elasticity of the gas.

SPEKTER, ERWIN, was born in 1806, at Hamburg, where his father, a native of Hanover, was settled as a merchant. During the siege of Hamburg, in the winter of 1813-14, his parents took refuge with their family in the house of the banker Dern, in Altona, where there was a good collection of pictures, and where Erwin made the acquaintance of the painter Herterich, who was also living in the banker's house, and had a studio there. In this studio, in which he spent nearly all his time, Erwin Speckter acquired his first instruction in art, and his natural taste rapidly developed itself. In 1818, when his father's bank became insolvent, the young Herterich erected a lithographic press, the first which was established in North Germany, and young Speckter made some attempts in portraits, and in drawings to illustrate the old Reinecke Fuchs and other old stories of the country.

In 1823 Von Rumohr returned to Hamburg from his second visit to Italy, and, being struck with admiration of the promising talents of Speckter, urged him on in his career, and particularly to study the movement of art in and about the neighbourhood. This led to an artistic tour which he performed in 1823, with a brother and another artist friend, through Schleswig and the neighbouring country. The chief objects of this journey were the carved altarpiece of Hans Brügmann at Schleswig (lithographed by Böhndel) and the picture of Menlling at Lübeck, the latter of which Speckter and his brother Otto published in lithography. These early works gave Speckter's mind the peculiar bias which at that time characterized the majority of the younger artists of Germany, and the arrival of Overbeck's picture of Christ's Entry into Jerusalem, for the Marien Kirche of Lübeck, confirmed the conviction of Speckter that the destiny of art in Germany, with the addition of academical drawing, Overbeck's picture has been lithographed by Otto Speckter. At this time Speckter's chief labours were indiscriminate studies from nature of every description, and portraits: his first oil-picture was a view of the Mansion-house of the House of Commerce. Overbeck's picture seems to have kept him by a species of awe from attempting such high subjects himself; he was also always guided in his studies by Rumohr.
In 1825 he visited Munich, and placed himself under the direction of Cornelius, who expressed great admiration for his ability; and, after the completion of his cartoon of the Resurrection of Lazarus, allotted him one of the stalls or loggias in the Munich Court, which he was to paint. He was much fresco with incidents from the lives of the greatest modern painters. Cornelius selected Fra Giovanni da Fiesole for Speckter, as peculiarly suited to his taste. Speckter, then almost forty years of age, received the commission with exultation, but he did not live to execute it, for the Fiesolets he was not ready for the frusco until many years after this date.

In 1827 Speckter returned to Hamburg, chiefly to be in the vicinity of the above-mentioned work by Overbeck, while he painted his picture of Christ and the Woman of Samaria; but the deep impression made upon him by Overbeck's pictures had a very prejudicial effect upon him, through his inordinate striving after abstract ideal representation. His own dissatisfaction with this work may be inferred from his immediate but still gradual change of manner; for in his next work, the Women at the Tomb, there is a far greater attention to dramatic probability, and a more prominent part given to colour. He painted at this time also several beautiful miniatures from sacred subjects. In 1830 he appeared in entirely a new character in his arabesque and mythological decorations of the house of the Syndics Sleevving near Hamburg. In September of this year, after the completion of these, he set out by Berlin and Dresden upon a long-intended journey to Italy. The constrained taste which had hitherto possessed him, though it was gradually yielding to his own experience, was finally subjected by the contemplation of the Italian works in the Museums of Berlin and Dresden, especially those of Filippo Lippi, Raphael, and the great Venetian masters.

Speckter arrived in Rome in January, 1831, after a short stay at Venice, from which is dated the first of his very interesting series of Letters from Italy, which, by the advice of Rumohr, have been recently published. He remained in Italy, chiefly at Rome and Naples, until the summer of 1834, when he was called to Hamburg to paint in Fresco the villa of Abendroth, then recently constructed by A. de Chatassmeuf. In Rome Speckter confined his labours almost exclusively to studies, and these are in the general spirit of Italian art, and quite in a different style from his early efforts. The only oil-paintings he painted in Rome were two of Allaso Women, in ideal characters, and a large picture of Saxon and Dalilah, which was purchased by Rumohr.

In the spring of 1835, though suffering greatly from asthma, Speckter commenced his frescoes; he had in the interim completed three of the principal cartoons: the subjects are from Greek mythology, and the figures are half the size of life. Two of the subjects were,—1, a winged Pegasus from the Muses, and the Hippocrene fountain, which springs from the kick of the horse (M. de Chatassmeuf describes the nymphs or goddesses of this piece as the Graces); 2, the Graces, in a grove of laurels, decorate the bow and quiver of Cupid, and offer him a cup of ambrosial drink; and 3, the Fates, lulled by the lyre of Cupid, have ceased their labours, and recline on couches; the distance is concealed by a curtain. The first of these designs, distinguished for the exquisite beauty of its forms, was completed in fresco, and the second was partly executed; the third was not commenced. His weak state forced Speckter to leave his work at the beginning of November, and he died on the 33rd of that month in 1835, deeply lamented by his friends, and by none more than Rumohr, who wrote a short account of the character, which is incorrect, and the biographical notice of him which precedes his letters. These letters, published in 1846, under the title of 'Letters of a German Artist from Italy,' (Briefe eines deutschen Küstlers aus Italien, 1832-1846, Leipzig, 1846), are full of interest in matter and reflections on art. Speckter's whole career is a remarkable instance of the power of nature over convention, which was not unknown to the modern artists. The personal attractions of art is gradually drew him from an abstract conventional system, in which art was only secondary to a peculiar sentiment independent of it, to the art itself, and for its own sake. Speckter's conversion to nature is not singular in the history of modern German art.

(Scrips. already mentioned.)

SPECTRUM, in optics, is a name applied to the elongated image of the sun which is formed on a screen in a darkened room when a slender beam of the sun's rays passing through a perforation in the wall or in a window-shutter has been afterwards transmitted through a prism formed of any transparent medium [Drasanzas, F. C.; and, for the dark lines, observed by Nipkow, in C.].

If a prism of crown-glass, and one of flint-glass, have their refracting angles of such magnitudes that the spectrum formed by one shall be of the same length as that which is formed by the other, and the red and violet rays of the spectrum may be in contrary directions, the red and violet rays of the spectrum will be united so as to proceed parallel to one another in the emergent pencil, but the dispersions of the intermediate rays, the magnitudes of which are diminished, will be preserved, and some colour will still remain in the image formed on the screen which receives the refracted pencil. This circumstance was first observed by M. Clairaut, and the coloured image was called by Dr. Blair a secondary spectrum.

When a spectrum is formed by a prism of crown-glass, the mean refracted ray meets the screen at the boundary-line between the blue and green spaces; but if a spectrum of equal length be formed by a prism of flint-glass, the mean ray, instead of being at that boundary, will be nearer the red or least refracted end of the spectrum; consequently, with flint-glass, the rays which suffer the least refraction occupy a smaller space, and the scale of those which experience by fraction occupy a greater length in the spectrum than they, respectively, occupy in a prism formed of crown-glass. On the other hand, when the one is of a perfect crystal the mean ray is nearer the violet end than it is in a spectrum formed with a prism of crown-glass, so that the least refrangible rays occupy a greater, and the more refrangible ones a less space in the spectrum produced by the latter medium. Hence, if a pencil of white light be made to pass through two prisms, one formed of crown and the other of flint glass, their refracting angles being such that the red and violet rays of the spectrum are united, there will be formed on the screen a short or secondary spectrum, its upper part, or that which is near the violet end, consisting of the green light which remains un refracted, and the lower part of the light formed by the union of the red and violet rays. If the bar of a window-frame be observed through two such prisms combined together, the upper side will appear to be fringed with green and the lower side with a purple tint arising from the blending of the red and violet rays.

But if a pencil of white light be made to pass through two prisms, one formed of crown-glass and the other of rock crystal, their refracting angles being such that the red and violet rays of the first spectrum are united, there will be formed a secondary spectrum in which the lower part is green and the upper part purple; or, if the bar of a window-frame be observed through such a combination of prisms, the light through the union of the object-glass, and, in the other, it will be surrounded by a fringe of purple light. (Breuer, Treatise on New Philosophical Instruments, p. 328.)

Prisms of three different media might be formed which would unite the rays of three different colours; the uncompounded colours, which are inclosed in the prism, are discernible, and that which remains when two differently coloured rays only are united, and Sir John Herschel, in the 'Encyclopedia Metropolitana' (art. Light, No. 445), proposes to call it a primary spectrum, the object-glass of which might be obtained by using a greater number of prisms, for the purpose of uniting with the former the rays of other colours; but the elimination of light caused by the employment of so many media would be considered an evil great enough to be proposed to correct.

Sir David Brewster has given the name of tertiary spectra to the images formed by the union of two prisms, such remains when the red and violet rays are united by causing a pencil of white light to pass through two prisms of the same medium, as flint-glass, with their refracting angles in opposite positions; in this combination the refracting angle of one
prism is greater than that of the other, and the pencil of light is about 1/8 in. in breadth) in the wall or in the window-shutter of a darkened room, and then through a still narrower aperture in an opaque screen placed a few inches from the object-glass of a telescope (the two apertures being parallel to one another and with the object-glass of the telescope), fringes produced by the diffraction of light at the edges of the aperture, being viewed through the telescope, assumed the appearance of spectra similar to those produced by the refraction of light through a prism of some transparent medium.

To these images Fraunhofer gave the name of spectra of the first class; they are composed of variously coloured light, the tints melting into one another by insensible gradations, and they exhibit dark lines as in the usual prismatic spectra.

When there was placed before the telescope a grating consisting of many very slender wires parallel to one another and to the aperture in the wall, and having very narrow intervals between them, such as a screen would form on either side of the image of the aperture in the wall, and beyond this, on each side, a series of spectra each consisting of variously coloured spaces, of homogeneous light, separated from one another by dark lines; these he called spectra of the second class.

When two linear apertures only were made in the screen at the object end of the telescope, there appeared in the field, between the image of the aperture in the wall and the first of the spectra, on each side, what Fraunhofer designated imperfect spectra of the second class; these consisted of coloured spaces similar to those in the spectra of the first class, but without the dark lines; and where a double linear aperture only were formed in the screen, there appeared, between the image of the aperture and the nearest imperfect spectrum of the second class, other spectra less distinctly formed than the latter, but without the dark lines; these he denominated spectra of the third class. No other classes of spectra than those which have been mentioned were observed on increasing the number of the apertures in the screen.

Many beautiful varieties of spectra were observed by Fraunhofer when the light was transmitted through three or a greater number of small circular apertures in a metal plate, and also through two frames, each carrying a number of slender wires much closer set together than the former; so that the wires in one were at right angles to those in the other.

*SPECULARIA* (so called from Specularia, Venus, a genus of plants belonging to the natural order Campanulaceae; it has a rotund capsule, a linear-oblong prismatical capsule opening by lateral pores between the calyx-segments. In other genera of the same Order, the capsule is linear, as in *S. hybridus* which it has been separated by recent systematicists. The species are small annual plants inhabiting the regions of the Mediterranean and the temperate parts of Europe. One species, the *S. perfoliata*, is a native of North and South America.

*S. hybridus* has a simple or branched stem, the leaves slightly crenate, wavy, oblong, sessile, the lower leaves spatulate; the calyx scarious, the segments lanceolate, longer than the corolla, shorter than the ovary. This plant is a native of the corn-fields of Great Britain, and is found commonly throughout the territory of the Mediterranean. There are several other species of this genus, all of which are worth cultivating on account of their showy flowers. The seeds should be sown in the open ground, where it is intended the plants should remain. By sowing the seeds in the autumn an early blossoming may be ensured in the following summer, and by successive sowings in the spring and summer they may be made to blossom for several months during the summer.

(Don. Gardener’s Dictionary; Babington, Manual of British Botany.)

**NOTE.** JOHN CHARLES SPENCER, THIRD EARL, will be best remembered by the title of courtesy. Viscount Althorp, which he bore from his birth, through, it may be said, the whole of his public life, and until within a few years of his death. George John, second Earl Spencer, and Lavinia, eldest daughter of P. C. S., No. 157.

Charles Bingham, first Earl of Lucan; and was born on the 28th of May, 1744. Like his father, he was deeply indebted for his love of literature and his munificent expenditure in the collecting of rare books, he was educated at Harrow; whence he was sent to Trinity College, Cambridge, where he took the honors of A. M.

In April or May, 1804, towards the close of the second session of the second Imperial Parliament, Viscount Althorp entered the House of Commons as one of the members for Oakhampton. A vacancy appears to have been made for him by the resignation of James Strange, Esq. On the 11th of February, 1806, on the formation of the Whig ministry of Mr. Fox and Lord Grenville, in which his father Earl Spencer took office as Secretary of State for Foreign Affairs, Lord Althorp was appointed one of the Junior Lords of the Treasury; and this appointment having vacated his seat, he offered himself for the University of Cambridge, which had been represented by the late premier, Mr. Pitt; the other candidates being Lord Henry Petty (now Marquess of Lansdowne), who was the new Chancellor of the Exchequer, and the present Lord Palmerston. The votes were, for Lord Henry Petty 381, for Lord Althorp 135, for Lord Palmerston 128.

To the next parliament, which met in December, 1806, Lord Althorp was returned at the head of the poll for the county of Northampton; and, after a severe contest, the opposition were, for his lordship, 2085; for the other member, William Ralph Cartwright, Esq., 1990; for Sir William Langham, Bart. (the defeated candidate), 1881. After this his lordship continued to be returned for Northampton for 17 years, from 1807 till March, 1824, when the Grenville administration was dissolved in March, 1807; nor did he again hold office till the accession of Lord Grey and his friends to power in November, 1830. During all this interval, although he did not come forward in debate so frequently as some other members, he was regarded as one of the steadfast supporters of the Opposition in the House of Commons; and, while he was making his way to the highest place in the confidence of his party, it is said that he always felt that there was no man on either side of the House whom the public generally held in greater respect for his universally admitted patriotism and freedom from the narrowness and vassalage of faction. Yet he was no temporizer for half- and half politician. On all the great questions of the day he took a decided part; and on most of the occasions on which his party made a stand against the government, he went as far with them as any of his colleagues.

In 1807, for instance, when he was supporting an address to the throne for a reduction of the number of the Lords of the Admiralty, and opposing the suspension of the Habeas Corpus Act, the maintenance of so large a standing army, the renewal of the Alien Act, and the additional grant to the Royal Dukes; in 1819 moving for an inquiry into the State of the Nation; in 1823 moving for a repeal of the Foreign Enlistment Bill, and opposing the bill for removal of the Irish soldiers; and in 1824 moving for a Committee of Inquiry into the general state of Ireland; in 1825 opposing the Suppression of the Catholic Association; in 1828 moving the first reading of the bill to repeal the Test and Corporation Acts, and opposing the grant of 2000l. per annum to the family of the late Mr. Canning.

Lord Althorp was also prominent for several years, about this period, in a series of economical attacks upon the Tory administration, and his house was the resort of a powerful section of the Whig party, who considered him their leader in the House of Commons. There were few questions of public importance, over and above those already mentioned, in which he did not take a practical and useful share; and his sound judgment, under all the vicissitudes and excitement of Parliamentary affairs, amply justified the confidence and attachment with which he was regarded by the party. There was about him, indeed, so much reality of purpose, such unostentatious manners, a bearing and simplicity so characteristic of the English nation, that a few sentences from him were equivalent to an eloquent exhortation from the pulpit. For Mr. Canning was a man of great ability; and though he was not fortunate enough on all occasions to escape censure, we believe it may be truly said that such censure generally emanated from individuals whose views had been frustrated by his policy. If we except the supporters of the mild left politics, he was not less in charity with all men than they

VOI. II.—4 D
were in charity with him. 'Honest Lord Althorp' was the current phrase by which his Lordship was recognised by the House of Commons and the public for many years.

The House, it is true, has been often led by what are called the Whig parties, and the Whigs particularly have never been wanting, any more than it was during his leadership, in distinguished talents and rare oratorical ability. We doubt however whether amongst the many distinguished persons who formed Lord Grey's administration, a single individual could have been selected who would have combined in himself the support of the great measures of the day so much popular confidence and support, and would have carried them through parliament with an industrious patience and an earnest equal amiability equal to Lord Althorp. To the honour of the House of Commons, character in public men has an authority there which stands its possession in lieu of more striking qualities; and no Englishman of our age need be ashamed, on being reminded of the great orators of the last generation, that for several years the public business was conducted by a gentleman whose language was as plain as his appearance, but who never spoke without effect, because his hearers well knew that he had no object but the honour and prosperity of his country.

In respect to the great questions which have since entered into politics and made so much influence for the last four years on the legislation and statements of the day, we mean those connected with the emancipation of trade and commerce, we have reason to know that Lord Spencer warmly sympathised in the progress of these liberal measures; and there cannot be a doubt that his influence and support would have been given to the policy and measures of 1846.

It will be remembered that upon the address to the crown in 1841, Lord Althorp was selected for the Chair of the House of Commons. In August, 1841, when the Whigs were in power and the stability of Lord Melbourne's government was at issue, he moved the address on that occasion, and emphatically declared himself in favour of free trade. There was an opposition of course, within a short period of his death, when he lost the confidence of a portion of his agricultural friends by an open declaration in favour of a total repeal of the corn laws; and we question whether Mr. Cobden ever gave greater proof of his attachment to the cause of free trade in the middle or the upper ranks than when he could appeal to the recorded sentiments of those devoted and so distinguished a farmer as Lord Spencer.

But to return to the narrative: In November, 1827, the Whig section of the Gaderich cabinet fixed upon Lord Althorp to be chairman of a Committee of the House of Commons, which it was proposed to appoint to take into consideration the general state of the national finances, and the premier (the present Earl of Ripon) appears to have given a qualified assent to that arrangement. But it was defeated, after a communication had been made to Lord Althorp, and his lordship had signified his conditional acceptance of the invitation, by the opposition of Mr. Herries, the then chancellor of the Exchequer. This affair led to the resignation of their offices both by Mr. Herries, and Mr. Huskisson, secretary for the colonies, and to the breaking up of the administration.

On 8th January, 1828, the reader is referred to the 'Annual Register' for 1828, pp. 3-12.

On the accession to power of the Grey administration in November, 1830, Lord Althorp was appointed chancellor of the Exchequer. His position, and the sound ability which he evinced in the management of great political and economical questions, with the universal confidence in his integrity, made him the ministerial leader in the House of Commons. No man probably had ever filled the latter post who possessed less of the gift of oratory; but the clearness and sound sense of Lord Althorp were considered ample sufficient to make up for that deficiency. Nor were the expectations of his friends disappointed. The task of carrying through the House both the Reform Bill and the Poor Law Amendment Bill devolved principally upon him; and not only the candour and patience and complete command of temper (often in very trying circumstances) which he never failed to evince, but his mastery of both measures in all their details, the readiness and accuracy of his recollection, and even the talent of exposition and advocated the reform of those studies to produce a general conviction that the difficult work he had undertaken could hardly, looking to all considerations, have been placed in better hands.

The appointment of Lord Althorp to a high ministerial office in the House of Commons was attended with the serious drawback, that his father, Earl Spencer, having already attained to the age of seventy-two, Lord Althorp was very little to be seen and suddenly called away both from the House of Commons and from his office, which could only be held by a member of that House. In point of fact, the leath of Lord Althorp and the death of his father had been reluctantly, by occasioning this change, broke up the ministry. [WHITFIELD IV.] When the administration of Sir Robert Peel and the Duke of Wellington, which succeeded, was obliged to resign in April following, and the Whigs came again into power under the premiership of Lord Melbourne, Lord Althorp, now Earl Spencer, was, as well as Lord Brougham, left out of the new cabinet.

It was understood that he declined to take any office; and indeed he was reluctantly induced to resume the Chancellorship of the Exchequer after giving in his resignation when Lord Grey finally retired in July of the preceding year. There can be no doubt that in losing him, the remnant of the original Reform cabinet, now deprived also of Lord Durham, Lord Stanley, Sir James Graham, Lord Ripon, the Duke of Richmond, Lord Carlisle, Earl Grey, and Lord Brougham, lost one of its chief stays, notwithstanding that Lord Lonsdale, Lord Melbourne, Lord Palmerston, Mr. Grant (now Lord Glenelg), Lord Auckland, Lord Holland, and Lord John Russell still remained.

What is said of Lord Althorp by the writer of the Memoir in the 'Gentleman's Magazine' is the more valuable as the testimony of a political opponent: — 'His sincerity was never doubted, nor the integrity of his motives. ... Up to the hour of his departure, he was ever the representative of the democracy of his country, which had not less interest for the benefit of those who had done him so much good, and for the esteem of the House, if he did not support its popularity; and no minister ever retired into private life accompanied with warmer wishes for his happiness, or a more general feeling of good will.

Earl Spencer had always been strongly attached to agricultural pursuits; and now that he was no longer relieved from official occupation, but had nearly withdrawn altogether from the world of politics and public life, he devoted his time to his farm, with more eagerness than ever to practical farming, the rearing of cattle, the patronage of agricultural associations, and whatever promised to advance his favourite science. 'Regardless of expense,' as he used to say, 'I provide for the views which I have just quoted,' he was almost invariably present at all the great agricultural meetings throughout the country. Indeed he may be said to have been the father of many, as he certainly was the patron of all. He was for many years President of the Smithfield Club; and, in the year 1837, in the course of his address to its members, he suggested the formation of the Royal Agricultural Society. Earl Spencer was the first President of this Society in 1838-9, when the meeting was held at Oxford, and again in 1844, when the meeting took place at Southampton. In the formation and operations of the Yorkshire Agricultural Society he also exerted himself, and was in every way marked by zeal than by a sound discrimination. His Lordship was President of the Yorkshire Society when its meeting was held at Doncaster in 1843.

Lord Althorp's son, John, was one of the original members of the Roxburghe Club (for the reprinting of rare and curious tracts), of which his father was the first President. He was also Vice-Chairman of the Council of the Society for the Diffusion of Useful Knowledge; and he was a liberal contributor to the fund raised for the 'Biographical Dictionary' which the Society commenced. Lord Brougham dedicated to him his 'Discourse on Natural Theology,' published in 1836, in an address in which he says: — 'I inscribe the Preface of those studies to you, because you have devoted much of your time to such inquiries — are beyond most men sensible of their importance — concur generally in the opinions which I profess to maintain — and have even formed the design of giving to the world your thoughts upon the subject, as I hope and trust you now will be moved to do all the more for the present address. Lord Brougham's 'Dialogues on Instinct,' first published in his 'Supplement to Political Theory,' in 1840, are also supposed to be carried on with Lord Althorp, neither whose political nor agricultural pursuits, he says, 'had ever at any time prevented him from cultivating a sound philosophy.'

In the study of which much of his leisure is always consumed.'

Lord Spencer died at his seat of Wiston Hall, in Nottinghamshire, on the 1st of October, 1845. He had married, in 1814, Esther, only daughter of Richard Acklow, Esq., of Wiston; but she died on the 11th of June, 1818, without issue; and his lordship was succeeded in
the peerage by his next surviving brother, Frederick, now Earl Spencer. (Memoir in Gentlemen's Magazine for Nov. 1846; Annual Register; Private Communication.)

SPEHERADA, a fossil plant from the Yorkshire coast. SPEHEROCOCITES, a genus of fucoidal fossil plants, from the oolitic series of the Yorkshire coast. (Prelim.)

SPEHERODUS, a fossil genus of fishes from the oolitic and cretaceous strata. (Agassiz.)

SPHERONICHUS, a genus of fossil Echinoderma from the Silurian and Devonian strata. (Hisinger.) Von Buch includes them in his family of Cycstidae.

SPHENACANTHUS, a fossil genus of fishes from the coal formation of Scotland. (Agassiz.)

SPHENOCUBIA, a genus of fossil fishes from the lias and wealden series of England. (Agassiz.)

SPHENOPHYLLUM, a fossil genus of plants from the coal formations of Europe and North America. (Brongniart.)

SPINDIFODA, a genus of fossil fishes from the London clay. (Agassiz.)

SPIDER. (Arachnida, P. C.) The habits of spiders have recently formed the subject of an interesting and valuable research by Mr. Blackwall, for the Advancement of Science, by Mr. Blackwall. This report, which is printed in the Transactions of that body for 1844, is full of new and curious matter. It touches on many points which have hitherto been imperfectly understood. There are also some valuable memoirs on the same subject in the later volumes of the Linnean Transactions, and several papers on new forms in the Annals of Natural History, by other authors. Also an important and elaborate account of the anatomy of some species by Mr. Tulk.

Of the discoveries of Mr. Blackwall the most interesting and extraordinary are the sexual intercourse of these animals, and to the purposes served by their palpi in aiding in the continuation of the species. The facts made known on this subject are among the most singular discoveries of late years. For their full and proper history, we must refer to the report mentioned. We shall quote only a passage respecting the reproduction of the amputated palpi:

"When the palpi of male spiders which had been amputated before the penultimate molt are reproduced also. (See experiments 8, 10, 11, 14.) Unexceptionable evidence in support of this singular fact is to be found in their reduced dimensions and integrity of form; but it will scarcely be denied that the original parts of the segments must have been removed with the detached palpi. That the function of the sexual organs is not in the least affected by their reproduction there exists the same and necessary proof. In the last of the experiments, having for their object the determination of the mass of sexual organs in male spiders, recorded in this report, the male Tegevaria civilis, stated to have possessed the right palpi, and a single pair of left palpi, was observed to have a mass of sexual organs that was the subject of experiment 8 in the foregoing series; consequently its sexual organs had been reproduced, yet the fertility of its mate bore ample testimony to the unimpaired efficiency of their generative agency." Mr. Blackwall adds some very curious facts respecting the reproduction of spiders' limbs generally:

Physiologists, in conducting researches relative to the formation of the limbs of insects, seem to have limited their investigations to the legs of those animals; whereas in the experiments detailed above, the palpi and spinners, as well as the legs, were operated on; and all these parts are found to be renewed, and afterwards to have their dimensions enlarged at the period of moultmg only; it appears also, that if a part of a limb be amputated, as the tarsus of a leg or the digital joint of a palpus, the whole is reproduced, all the joints of the new limb, though small, being proportionato to those of the corresponding limb on the opposite side, with the exception of the digital joint of the palpi of male spiders when the sexual organs are not reproduced, which is usually some 1.5 the size and half by that circumstance.

The following observations respecting the non-stopcrotically occasionaly presented by spiders, are of no small consequence in their bearing on specific determinations:

Variation in the colour and size of spiders of the same kind, resulting from differences in age, sex, food, climate, and other conditions of a less obvious character, as they conduct largely to the introduction of fictitious species, have long engaged the attention of arachnologists, while those arising from extraordinary organic modifications, in consequence perhaps of their less frequent occurrence, have been almost entirely overlooked. The importance of which cases of the latter description possess, in relation to physiology and systematic arrangement, will be best illustrated by a few examples:

1. A supernumerary eye, situated between the two small ones constituting the anterior intermediate pair, has been observed in an adult female Theridion filipes. The total number of eyes possessed by this individual was nine, and their arrangement symmetrical.

2. An immature female (Thomisus cristatus) had the two lateral pairs of eyes only; the four small intermediate were altogether wanting, not the slightest rudiment of them being perceptible even with the aid of a powerful magnifier.

3. A short but perfectly formed supernumerary eye, connected with the base of the taral joint of the right posterior leg on its outer side, has been noticed in an adult female Lycosa cambarica.

4. Deficiency of the right intermediate eye of the anterior row has been remarked in an adult male Lycosa cambarica.

5. The left intermediate eye of the posterior row was perceived to be wanting in an adult female Epeira icicinata, and the right intermediate was the same.

6. An adult female Cninospila atrata was found to be without the left intermediate eye of the posterior row.

7. The right intermediate eye of the posterior row in an adult female Epeira icicinata had one-eighth of the natural size, being merely rudimentary.

SPIKENARD. (Ramarstachis, P. C. S.)

SPLANANTHUS (from evulve, a spot, and dros, a Sower, because of its dots or specks), also an important and elaborate account of the anatomy of some species by Mr. Tulk.

S. acranthus has a branched diffused stem, opposite stalked broadly ovate leaves, obtuse at the base, truncate or somewhat cordate. The pedicels are one-headed, longer than the leaf. The heads thick, ovate, and discoidal. The scolotha cicatrices at the angles, bi-asturate or awl-shaped. The whole plant, but especially the involucres and receptacles, as a powerful stimulant of the salivary organs.

(Lindley, Flora Medican.)

SPINELLI, PARRI; a celebrated old Italian painter, was the son of Spinello Aretino, and was born at Arezzo, apparently about 1388-90, though his father was very old, upwards of seventy. This conjecture however rests only upon Vasari's statement concerning his date of birth, and the assertion that Parri died when he was fifty-six years of age, and on the date 1444, which is on the altar-piece of San Cristofano at Arezzo, which is attributed to him.

He was first instructed by his father, and was afterwards employed by Lorenzo Ghiberti in Florence as an assistant in preparing the celebrated gates of the Baptistry of San Giovanni, which were executed between 1402 and 1424. He painted chiefly in Arezzo, and Vasari enumerates many of his works, but few now exist. He returned to Arezzo, says Vasari, upon the death of his father, and after many years' absence, from which it would appear that the father lived further in the fifteenth century than is at present supposed; he is known to have been living in 1408, and his death is supposed to have happened about this time. Vasari's statement that he died in 1400 is probably a mistake as well as an error, as the account of Parri's assisting Ghiberti and returning to Arezzo at the time of his father's death and after many years' absence, is a complete contradiction to it.

Parri was an excellent colourist, and was the best practical fresco painter of his time; his draughtsmanship was also good, but his figures were too large in proportion; Vasari says some of them measured as many as eleven heads in height, and yet they were not ungraceful.

Varese, Vite d'Arte, &c.)

SPIRIFER, the earliest generic name assigned by Sowerby to a large group of fossil Brachiopoda, from the Paleozoic strata. (Delafield, Orthis, &c., since have been discovered from the Carboniferous.)

SPIRITUAL COURTS (Ecclesiastical Courts, P. C. S.)

412
SPIROGLYPHUS, a genus of fossils from the mountain Jemstones of Ireland. (M'Coy.)

SPIROPORA. (Carceora, P. C. S.)
Spirex, an undetermined, probably Zoophytae genus of Silurian fossils. (Murchison.)

SPRANGER, BARTOLOMAEUS, a great maniriert, but a celebrated painter in his time, was born at Antwerp in 1569, a wealthy merchant, and after he had received instruction from several masters at Antwerp, he visited Paris and Italy, where at Milan he placed himself with Barnardo Gatti, called Solaro. From Milan he went to Rome, where he found a patron in the Cardinal Farnese, who introduced him to Pope Pius V., who commissioned Spranger to paint a picture of the Last Judgment, gave him apartments in the Vatican, and appointed him his painter. This picture of the Last Judgment, which contained about five hundred heads, was painted on a large sheet of copper, and after the death of the pope it was fixed over his tomb in the church of Santa Maria Maggiore, but must have been long since removed.

In 1576 Spranger left Rome to enter the service of the Emperor Maximilian II., at Vienna, to whom he had been recommended by John of Bologna. After the death of Maximilian he remained in the service of Rudolph II., who ennobled him in 1588. He visited his native place in 1602, after an absence of thirty-seven years, and was treated with great distinction by his countrymen. He returned again to Frankfort, where he was about 1626, spending in that town his last years. There are nineteen pieces by Spranger in the gallery of Vienna, and many in other German collections. He painted with facility, but his figures are heavy, gross, and distorted; he painted mostly religious and mythological subjects, which were utterly unfit for his style.

(Fiorelli, Geschichte der Malerei, &c.)

SQUALORIA, a genus of fossil fishes from the lias of Dorsetshire. (Hill.)

SQUARCIONE, FRANCESCO. This painter, celebrated for his superior acquirements as well as his great school and rich collections of works of art, was born of a good family in Rome in 1571, and after having lived in Greece and Italy, lived there in great affluence and distinction until his death in 1744. His house was one of the chief attractions in Padua. He was the master of Andrea Mantegna, who lived some time in Squarcione's house. From his very various school (he had 137 scholars) he was called the father and primo maestro of painters. He appears to have been more engaged in teaching than in practising the art.

(Venezian School of Painting, P. C., vol. xxvi. p. 212.) Vasari terms him erroneously Jacopo Squarcione.

(Ridolfi, Vita de Pittori Veneti, &c.)

SQUATTIA, a genus of carinuligous fishes, of which the Fish of the name of Brunnhusen. They differ from all the other sharks in the position of the mouth, which is cleft at the extremity of the snout; and not placed below, and in the position of the eyes, which, instead of being on the side, are placed above the mouth. The body is broad and flattened horizontally; the head is round. The dorsal fins are placed farther back than the ventrals, and there is no anal fin.

STADE DUTIES are so called from Stade, in the kingdom of Hannover, a town situated on the right bank of the Schwinge, three or four miles from where it falls into the Elbe, and 22 miles west by north from the city of Hamburg. The name Brunnhusen-Tolle is now more commonly used, from the village of Brunnhusen, at the mouth of the Schwinge, where there is a customs-house and a royal guard-ship, and where vessels are collected which are levied on vessels and merchandise passing up the Elbe. The original duties, which were regulated by a treaty made in 1691, were light, but were gradually increased by the Hanoverian government till they amounted to about 44,000 a year. The duties levied were about 42 per cent. of all sundries, more on some commodities and less on others. British vessels by a proclamation of Geo. II., December 1, 1736, were allowed under certain regulations to sail directly up to Hamburg, without coming to anchor at thealternatives of the Schwinge, as other foreign vessels were obliged to do.

By a convention between the King of Hanover and the other United States, an undertaking of Emperor of Austria, King of Prussia, King of Spain, King of Saxony, King of Hanover, Duke of Mecklenburg-Schwerin, Duke of Anhalt-Cöthen, Duke of Anhalt-Dessau, Duke of Anhalt-Bernburg, Free and Hanseatic town of Liibeck, and Free and Hanseatic town of Hamburg),

dated April 13, 1844, in conformity with articles 108 and 116 of Act of Congress of Vienna, of June 9, 1815, the Brunsheam Tolls were revised, regulated, and settled according to the convention.

By a treaty of commerce and navigation between the Queen of England and the King of Hanover, signed at London, July 32, 1844, British and Hanoverian vessels arriving at, or remaining at, any of the ports of either country, are mutually subject to no other or higher duties or charges than those which are now or shall hereafter be imposed upon the national vessels of the two countries on their arrival at, or remaining at, any of the ports thereof. All articles of the growth, produce, or manufacture of Great Britain or Hanover, which are or shall be permitted to be exported or imported in British or Hanoverian vessels, are mutually allowed to be exported or imported in vessels of either country, and no distinctions of duties or drawbacks shall be made. By article 6, 'From and after the 1st day of October, 1845, no other or higher duties or tolls shall be levied, as regards the tolls or charges known by the name of the Stade or Brunsheam tolls and charges, on British vessels passing up the Elbe to the point where the tolls of the Upper Elbe commence (that is to say, up to and including the town of Hamburg), or upon the cargoes of such vessels, than the tolls and duties which are specified in the convention between the Elbe-bordering states, which was signed at Dresden on the 19th of April, 1844, and in the separate articles, regulations, and rules of that convention.' However, to the following articles of British produce and manufacture (that is to say, yarn, thread, manufactures of cotton, wool, and linen, tin and tin plates, articles of iron and steel, iron crucibles, earthenware, and all sorts of ironware, including similar alloys of metals and manufactures thereof), it is agreed that the duty or toll to be levied, whether in British vessels or in vessels of any of the Elbe-bordering states, shall be only two-thirds of the duty or toll specified in the table.

The treaty is to continue in force till January 1, 1854.

STAINHAM, a formerly a market-town (and described as still being one in the Article Gloucester, P. C.), in the lower division of Wiltshire hundred, the civil and ancient county of Gloucester, about 3 or 3½ miles West of the town of Stroud, and about 30 miles N.W.S. of the town of Gloucester, and about 7 miles E. W. of Gloucester. The adjective to its name, St. Leonard, serves to distinguish it from two other Staines in the county, namely, the adjacent parish of King's Staines and the parish of Stanmore, nearly Winchcombe and about 1½ miles from the county. The area of the parish is 910 acres; the population at the different enumerations was as follows:—1801, 599; 1811, 608; 1821, 576; 1831, 942; 1841, 985; 1851, 966; 1861, 1088; 1871, 1201, namely 192 inhabited, and 19 uninhabited. There were none building. The village consists of three or four small streets meeting at the church, which is dedicated to St. Swithun, and is an
antient cross-church, with a tower at the intersection. The architecture is partly of the early English period, partly of later date. This church formerly belonged to a Benedictine priory, but in 1539, after the Reformation, it afterwards became a cell to Gloucester Abbey. There are some remains of the conventual buildings, which have been converted to domestic purposes. St. Leonard Stanely was annually met in this church in the month of July by the monks of the priory.

The church was produced or accelerated by a fire which, in A.D. 1686, destroyed nearly the whole town: it has some share in the clothing manufacture of the district, and has two yearly fairs, but they are of little importance. The living is a perpetual curacy of the clear yearly value of 200, but without a glebe-house fit for residence, in the rural deanery of Stonehouse, in the Archdeaconry of Gloucester, in the diocese of Gloucester. There were in the parish, in 1833, three small day-schools; one, with a small endowment, contained 14 children, the other two contained 42, giving a total of 56 children (25 boys and 31 girls), or only one in seventeen of the population, according to the census of 1831, under daily instruction. There were two Sunday-schools with 305 children, namely, 141 boys and 164 girls. The parish of St. Leonard Stanely is included in the parliamentary borough of Stroud.

(Parliamentary Papers; Ordealance Map; Foebroke's Gloucestershire.)

STANZIONI, MA'ASSIMO, Carullieri, a celebrated Italian sculptor, was born at Naples in 1855. He was the pupil of Caracciolo, but became afterwards the imitator of the great Bolognese painters, especially Guido Reni; he was called the Guido of Naples, and is considered the most correct of all the imitators of individual painting, painter, and was also distinguished for his frescoes. There are several excellent works by Stanzieni in the church of the Certosa, now an hospital, at Naples, especially the picture of St. Blasius painting the rules of order to his monks. In the same church is a picture of a dead Christ and the Marys, which, as it had somewhat darkened, Spagnoletto, through jealousy, persuaded the Carthusians to wash with a corrosive water, which completely spoiled it. Stanzieni, disgusted with the baseness of the act, would not restore it, preferring to leave it as a monument of Spagnoletto's meanness. Stanzieni died at Naples in 1868. He had a numerous school, and he left many notices of Neapolitan painters, which were used by Donizetti, Vite de Pittori Napoletani, &c.; Lanzi, Storia Pitteria, &c.

STARS, SHOOTING. [SHOOTING STARS, P. C. S.]

STATICE (from the Greek statif, intended to be used in the active sense, to 'stop,' so named from its supposed property of restraining hemorrhages), a genus of plants belonging to the family of compositae. The flowers are with 5-parted corolla, the calyx scarcely above, the capsules not bursting.

S. carduana has narrow oblong leaves on long petioles, sometimes more than a foot long. The flowers are on long stems on the margin. The scape is round, smooth, slightly scaly, and terminated by a panicule of numerous branches, which bear the flowers on the upper side only. The flowers are alternate, erect, mostly in pairs, but appear singly in consequence of one expanding before the other. The calyx is funnel-shaped, scarious, and pink at the edge, 5-angled, the angles ciliate, and ending in long sharp teeth. The petals are oblong, longer than the calyx, and of a bluish purple colour. This species is a native of North America, where it is called the Marsh Rosemary. The root is a very powerful astringent, and is used as an application in aphthae and similar affections of the mouth and fauces; it has been employed with success in cancerous ulcers.

S. Limonium, Sea Lavender, is a British species, and has much divided corymbose branches curved outwards; the ultimate subdivisions elongated with unilateral rather distant flowers, the flowers of the inflorescence less than half the length of the calyx, with a short pedicel and four ascending or intermediate teeth; the bracts obtuse, the outer ones large, the margins tinged with pink.

S. sphacelata has spathulate leaves narrowed into a broadly winged stalk; the calyx segments blunt, entire, and without intermediate teeth.

S. reticulata has spathulate leaves narrowed into a flat stalk, somewhat acuminate behind; the lower one provides a much divided bract, of which the lower are barbed; the calyx segments acute, denticulate. It is found in muddy salt marshes at Norfolk.

(Babington, Manual of British Botany; Lindley, Vegetable Kingdom.)

STATUTE (Scotland). It would be difficult to explain the character of the statute law of Scotland, the method in which it was sanctioned, or the constitution of the bodies by which it was passed. All the light that probably is to be obtained on the early history of the statute-law has lately been embodied by Mr. Campbell in his Historical and Critical analysis of the Scottish Statutes and Old Laws, published by the Record Commission. 'Whatever,' he says, 'may be the case in other countries, it is not easy in Scotland to distinguish the ancient legislative court or council of the sovereign from that which discharged the duty of counselling the king in judicial proceedings. The early lawyers, indeed, enacted statutes by the advice of the 'bishops, earls, thanes, and whole community,' or 'through the common counsel of the Kyng.' But during the reigns previous to Alexander III., we find the king also deciding causes in a similar assembly of magnates: while laws of the greatest importance, and affecting the interests of the whole country, were emitted by the king and his 'judges.' It is probable that the practice of the assembly, legislative or judicial, of the principal barons, though irregular, was in general an imitation of the parliament of England. But the introduction of the privilege of the southern districts of Scotland had been in a great measure partitioned among Norman adventurers, some of whom owed a double allegiance to the crown both of England and Scotland; and it was natural that the Scottish kings should borrow from the practices and opinions of the country with which they were earliest connected. A large proportion of the lowland population of Scotland were at the same time Saxon refugees from England. So early as the reign of David I. (1124) we begin to find that the municipal corporations had a voice in the ratification of the laws. 'The parliament,' says Mr. Innes, 'assembled by John Balliol at Scone, on the 9th of February, 1229, was probably the first of the national councils of Scotland which bore that name in the country at the time, although later historians have bestowed it freely on all assemblies of a legislative character. We have no reason to believe that any change in its constitution occasioned the change of term, which soon became in Scotland, as in England, the received designation of the general legislative council solemnly assembled. It was not till a few years later, on occasion of the dispute with the natives of the Hebrides, that the desire of the French king, procured the treaty to be ratified, not only by the prelates, earls, and barons, but by certain of the burghs of his kingdom. That treaty was finally ratified on the 29th day of July, 1237. At that time the seals of six burghs were then affixed to the deed, along with those of four bishops, four monasteries, four earls, and eleven barons. Notwithstanding this very formal ratification, however, it may be doubted, both from the peculiar phraseology of the deed itself, and from the silence of historians as to any meeting of a parliamentary nature in which it could have been voted, whether the parties stated as consenting, and especially whether representatives of those six burghs, were actually present as in a national assembly of parliament.'

The acts which were thus sanctioned—sometimes, perhaps, by the separate adhesion of the principal interests of the country, sometimes in assembles—were of a mixed character. Some were judgments in particular disputes, accompanied probably by the announcement of a principle on which such questions should thenceforth be decided; others were acts of executive authority; and others might be regarded as having the character of fixed and general laws. When these proceedings related to matters of private right, the recording instrument would be put into the hands of the party interested.

When the proceedings of the national council, says the authority already cited, 'related to matters of a more public nature, such as negotiations with foreign states, its earliest records were probably of a similar kind, and consisted of the speech or other declaration of the council that embodied the results of its deliberations. Perhaps the earliest instances of this kind that now remain are those important deeds of the reign of Alexander III., when, however, a more
artificial system must have been beginning to prevail. It would be still more interesting to ascertain the modes in which the more general ordinances and laws of the realm were enacted and recorded; but on this head the loss of many original documents appears to be irreparable. Judging, however, from the mutilated and imperfect transcripts of a later age, and from the analogy of the other states of Europe, it would appear that the more important and general statutes were framed into more capitulars, and incorporated into a writ, addressed, in the name of the king, to the chief ministers of the law in the different districts of the kingdom, requiring the publication and observance of them. The laws of the burghs are the ancestor of David I., as stated in the statutes of Alexander II., as found in the old manuscript compilations of lawyers, seem to be the fragments of various capitulars of this kind. The statutes of David I., `Assist Regis David,' are reported to be the oldest fragments of legislation in Scotland, and are partly, but not entirely, traceable to so early a period as the reign of the king with whose name they are associated. The burghal laws, `Leges Quatuor Burgorum,' constitute the oldest systematic collection of laws. They too may be referred to the reign of David, and though historians give him the credit of having planned the whole system of the municipal corporations, it is more likely that this code of laws was the work of the burgh denizens and residue which had gradually come into existence with the growing influence of the burghs. The coincidence between these early vestiges of Scottish legislation and the old law of England is remarkable. Both institutions in the burghs and in the technical phraseology is frequently used, which still belongs to the law and practice of England, but has long been disused in Scotland. Indeed, it is very clear that, before the attempt of Edward I. to reclaim the realm, there was no special legislation, no spirit between the two nations, and that Scotland generally followed or accompanied England in all her constitutional progress. There is still a more remarkable coincidence of institutions than that revealed by the declaration of James I., for the general code of the old laws of Scotland. It was, like the fragments mentioned above, attributed to David I., who had obtained the character of the Justiciar of Scotland; but it is undatable. In the thirteenth and seventeenth centuries it was very popular, as an undated early national code; but it was subsequently discovered to have many features in common with the compilation `De Legibus et Con- 
septudindibus Animis,' attributed to Ranulphe de Glanville, justi- 
ciar of England, and then it acquired the evil reputation of being a code prepared by Edward I., for the purpose of sub- 
jecting Scotland to the law of England. `Upon an accurate 
collation of the books,' says Mr. Innes, `it appears that the first four books of Glanvil contain in systematic arrangement, with some inconceivable exceptions, the same matter, almost in the same words, which the compiler of the `Regiwm' has put together, and that the character of the Roman law, has been only that of a compiler. Indeed, in the time of the Institutes of Justinian, all the barbarous laws of periods of bigotry or violence have ceased to be en- 
forceable. Since the Union of 1707, it has been considered, in conformity with the English doctrine, that an act passed by the British Parliament must stand, even if it appears to have generally happened that the full assembly only met on the first and the last days of a session: on the former the lords of the assembly were chosen; on the latter, the members of the house of commons were voted on, and sanctioned or rejected. The royal assent was given by touching the act with the sceptre; but some constitutional writers maintain that this was a mere court ceremony, and that an act which had passed the three estates became law without any sanction from the king. It became a principle which widely distinguished the legislation of Scotland from that of England, that in the former country statutes might come to be law by merely falling into desuetude. Of the statutes of the Scottish parliament, those only are now law which are said to be in viltro observantia. By this principle the statute law has silently modified. It was the charade to the chagrin of the Institute of Roman law, that the barbarous laws of periods of bigotry or violence have ceased to be en- 
forceable. Since the Union of 1707, it has been considered, in conformity with the English doctrine, that an act passed by the British Parliament must stand, even if it appears to have generally happened that the full assembly only met on the first and the last days of a session: on the former the lords of the assembly were chosen; on the latter, the members of the house of commons were voted on, and sanctioned or rejected. The royal assent was given by touching the act with the sceptre; but some constitutional writers maintain that this was a mere court ceremony, and that an act which had passed the three estates became law without any sanction from the king. It became a principle which widely distinguished the legislation of Scotland from that of England, that in the former country statutes might come to be law by merely falling into desuetude. Of the statutes of the Scottish parliament, those only are now law which are said to be in viltro observantia. By this principle the statute law has silently modified. It was the charade to the chagrin of the Institute of Roman law, that the barbarous laws of periods of bigotry or violence have ceased to be en- 
forceable. Since the Union of 1707, it has been considered, in conformity with the English doctrine, that an act passed by the British Parliament must stand, even if it appears to have generally happened that the full assembly only met on the first and the last days of a session: on the former the lords of the assembly were chosen; on the latter, the members of the house of commons were voted on, and sanctioned or rejected. The royal assent was given by touching the act with the sceptre; but some constitutional writers maintain that this was a mere court ceremony, and that an act which had passed the three estates became law without any sanction from the king. It became a principle which widely distinguished the legislation of Scotland from that of England, that in the former country statutes might come to be law by merely falling into desuetude. Of the statutes of the Scottish parliament, those only are now law which are said to be in viltro observantia. By this principle the statute law has silently modified. It was the chagrin to the charade of the Institute of Roman law, that the barbarous laws of periods of bigotry or violence have ceased to be en-
them to be enforced is to be found only in England. In many instances these acts have only been capable of enforcement in Scotland by reading, instead of English institutions, those of Scotland, which most nearly correspond with them—as, by subscription to newspapers, the 'Sailor's Weekly Record at Westminster.' The remedy for this evil appears to be, to incorporate with each act a clause stating the territorial extent of its application; and whenever it is intended that it shall apply to Scotland, to have clauses especially applicable to its enforcement in that part of the empire.

**STATUTE (IRELAND). [PARLIAMENT OF IRELAND, P.C.]**

**STATUTE OF FAUDS.** This name is applicable to any act which makes the question of fraud, or of the fraudulent character of a transaction, a matter of evidence, and is particularly applied to the 29 Car. II. c. 3, which is entitled 'The Statute of Frauds and Perjuries.' One object of the statute was to prevent disputes and frauds by requiring in many cases written evidence of an agreement. Before the passing of this statute many conveyances of land were made without any writing as evidence of the conveyance. An estate in fee-simple could be conveyed by livery of seisin, accompanied with proper words, and a use could also be declared by parol. No writing was necessary to convey any estate in possession, for such estate is technically said to lie in livery, but a revestiture could only be conveyed by deed. The statute of frauds declared that no estate of any interest not descended by generation in fee simple, of any interest not determined, of any interest not for a term for a term of years, or any uncertain interest in any lands or hereditaments, made by livery and seisin only, or by parol, and not put in writing and signed by the parties, &c., shall have the force of law. But the principal point to which the statute relates is the effect of deeds for more than three years, wherein the rent reserved shall be two-thirds of the full improved value of the thing demised, are excepted by the statute. Further, no lease, estates, or interest either of a term for a year, or of a term more, or of an estate by property, being by copyhold or customary interest, shall be assigned, granted, or surrendered, except by deed or note in writing. Another section of the statute provides that all declarations or creations of trusts by instruments signed in the presence of witnesses, or any having no predecessors, or any criminals, receivers, or any person, being copyhold or customary interest, shall be assigned, granted, or surrendered, except by deed or note in writing. Both these sections are repealed by the last Will's Act, 1 Vict. c. 26, which makes alterations in other provisions also of the Statute of Frauds.

**STATUTE MERCHANT. ACTON BURRELL, STATUTE OF, P.C. S. 22.**

**STEAM-VESSEL, SCREW.** While much has been done since the publication of the notices of screw-propellers under **Screw of Archimedes**, p. 111, and **Steam Vassar**, P. C., p. 610, in the practical application of such apparatus to steam-vessels, and results have been obtained which lead to the conclusion that this mode of propulsion is practicable upon a very large scale as well as in small vessels, and that it possesses some very important advantages over the use of paddle-wheels; the invention yet remains too experimental a state to justify any attempt to deal with it as a settled branch of science. Since the date of the articles referred to, in addition to vessels of more ordinary dimensions, the screw-propeller has been brought into use in the immense iron steam-ship now called the Great Britain, but which, while building, at Bristol, was sometimes referred to as the Mammoth, the dimensions of which, as given in the 'Ateneum' for 1846, p. 118, are 290 feet long and 50 feet broad in the widest part, drawing 16 feet. Its capacity is about 3000 tons, and the engines, consisting of four cylinders of 88 inches diameter and 72 inches stroke, are of 1000-horse power each. The Great Britain was launched, was fitted, on her completion in 1846, with a screw-propeller 164 feet in diameter, with six arms, mounted in the stern, and capable of being turned with great rapidity so as to allow the vessel to be steered in any direction almost immediately connected with the engines, and communicated its motion through an endless chain to a much smaller wheel fixed on the shaft, which constituted the axis of the propeller. The propeller was thus turned with a velocity exceeding that of the crank-axis in a ratio determined by the relative diameters of the larger and smaller chain-wheels. Thus mounted, and consequently the setting of the propeller was stepped on deck so as to be removable at pleasure, with wire rigging, and with every requisite for taking advantage of favourable winds, the Great Britain sailed from Liverpool on the afternoon of July 25th, 1846, on her first trans-Atlantic voyage, and reached New York on the afternoon of August 10th. After her fourth voyage (the second homeward trip), during which she was left for some time wholly dependant on the assistance of the screw-propeller, she was fitted with a new and much stronger propeller, weighing seven tons, of the same diameter as before, but consisting of only four arms or vanes; and she was at the same time fresh rigged, her number of masts being reduced to five, and the whole stepped upon the keelson. With these alterations, in an experimental trip made on the 30th of May, 1846, the Great Britain attained a speed of 11 knots, or about 13½ statute-miles per hour. *An important discussion upon screw-propellers, suggested by an account of a new steam-vessel called the Liverpool Screw, submitted to that body, was carried on during three days of the last week of the last session, and ended on February, 1844. In the course of this discussion, of which a full report was published in the 'Mechanics' Magazine,' vol. xl. pp. 291-299, it was remarked by Mr. Bennie that the speed of these vessels was at present very unequal, and that a ship which offered but little obstruction to the water, and yet acted upon it so as to exert full power in propulsion; and that a large portion of a complete screw having no useful effect, was lost in the direction of the blades. It was urged that the screws, being coplanar, or parallel, and the blades of the screw being coplanar or parallel, and the blades of the screw blades; thus doing away with the useless part of the surface. A perusal of the discussion alluded to will show that the engineers who took part in it were not quite agreed in their views of the action of such propellers, especially with reference to what is termed the 'slip,' by which appears to be meant the amount of motion absorbed by the propeller cutting its way through the water, instead of pushing the water forward with the speed of the ship. The amount of this slip might be deduced from the number of revolutions made by the screw, and the actual way made through the water. Without attempting to unravel this somewhat difficult question, upon the true comprehension of which the best shape, size, position, and velocity of the propellers must depend, we may observe with Mr. Farley that while the advantageous action of ordinary paddle-wheels is greatly impaired by variations in the degree of immersion, the submerged screw propeller, being wholly under water at all times, does not appear to be sensibly affected by any such alterations in the depth of immersion as are likely to take place in the roughest waves, as the greatest variations of draft are brought about by the lading of the vessel. When all circumstances were considered,' Mr. Farley observed, 'it might be safely concluded that vessels fitted with revolving submerged propellers would answer well for many of the regular voyages between the seas, in summer or winter; and, on an average, he thought that their passage would be performed at least as well (if not better) than those of any steam-vessels now in use; and with an economy of fuel, arising from such vessels making a more advantageous use of their sails, and less of their engine-power.' The absence of the ponderous paddle-wheels and paddle-boxes of an ordinary steamer greatly improves the sailing qualities of a screw-propelled vessel, while the arrangement of the machinery may be such as to render the vessel far more commodious, and, if desired, to leave the upper decks open from end to end. These, among other advantages, recommend this mode of propulsion for steam-frigates, and other vessels of war. The Princeton, an American steam-frigate, launched about the commencement of 1844, and mounted with Ericsson's transversal screw-propeller, affords a good example of the advantages of the invention as applied to masts and masts. This vessel, which, according to an account quoted in the 'Ateneum' for 1844, p. 205, from the 'New York Herald,' is of 700 tons burden and 250-horse power, has a submerged screw-propeller making 35 to 40 revolutions per minute, and is capable of making its way through the water at the rate of 14 miles per hour, or even somewhat more, is said to have beaten the Great Western in speed, although drawing at the time only 11½ feet.
time four feet more water, and exercising only two-thirds of her steam-power. The dimensions of the vessel are not given in the article quoted, but Mr. Brithwaite stated them, as follows: length over all, 165 feet long; beam, depth of hold 22 feet 6 inches, and draught of water 17 feet 6 inches. He also, if the report we have quoted be correct, stated the power of the engines as 400 indicated horse-power, and the velocity of the vessel as rather less than we have stated. In the absence of proof as to which statement is correct, we may observe that while Mr. Brithwaite's would indicate a very unusual and high proportion of power to tonnage, that of the the 'New York Herald' shows about the common proportion for fast vessels. The engines, according to Mr. Brithwaite, are of peculiar construction, having two steam cylinders or chambers, containing vibrating plates on the ends of the suspending pivots; these are coupled by connecting-rods to a main crank on the driving shaft, and the length of the first-mentioned cranks is so proportioned that their alternate vibrations shall give a rotary motion to the main crank, and thus act directly upon the propeller, without the intervention of chains or gearing. In a subsequent stage of the discussion this point was reverted to by Mr. Galloway, the advantage of turning the propeller by the direct action of the engines being, he said, generally acknowledged; indeed, he added, the method of driving it was nearly the only problem remaining for solution, and that difficulty would be overcome, he thought, naturally, from their vast advantage over paddle-wheels, in every respect but that, be universally adopted. Returning to the Princeton frigate, we may observe that it is evident, as stated in the report, that the novel principle of the English or the English paddle-wheels, as mounted would have the advantage over those of the usual construction in active service; for in that vessel the whole of the machinery, cranks, boilers, and furnaces, as well as the propeller itself, are below the water line, the top of the highest plates of the boilers being as much as four feet below, and therefore pretty secure against injury from shot, while, in the steam-frigates, and other steam-ships of the ordinary kind, the boilers and machinery, as well as the paddle-wheels themselves, are within destructive range. We may mention, although not directly affecting the use of the screw-propeller, that the Princeton is supplied with furnaces for burning anthracite, to avoid the production of smoke, and that she is ship-rigged, and so constructed that in favourable weather her screw may be unshipped, when she will sail well under canvas, a facility which can never be so perfectly attained with the use of paddle-wheels.

The Liverpool Screw, an account of which formed the basis of the discussion to which we have referred, is a small iron vessel, 46 feet long, 12 feet 6 inches beam, and drawing 9 feet 9 inches. This vessel was measured monthly with a screw of 3 feet 10 inches diameter, but it had been enlarged at three several times, and was, at the date of Mr. Grantham's account to one, 9 feet 4 inches diameter by 20 inches long, of wrought iron, and forming four short arms which united at 16 square feet, of which 13 only were immersed; a part of the propeller being constantly above the water. It was turned with a velocity of 25 revolutions per minute, by means of two high-pressure oscillating engines, working one crank upon the main driving shaft, without the intervention of gearing or bands; and the nominal power of the engines was 20 horses, though the effective power rarely exceeded 16½ horses. Though the proportions of this little vessel were not deemed favourable to a high speed, her length being only five times her beam, and her second diameter 38 feet, she was found, in a number of experiments, capable of being driven at a speed upon the Mersey, excepting the large sea-going vessels, and was proved to have a great superiority over other steamers in towing vessels at sea.

Many observers have stated that the usual position of the screw-propeller, immediately before the stern-post, does not appear either to be disadvantageous for the application of the propelling power, or to interfere with the action of the rudder. In this respect, it is to be observed, the effect of increasing the efficiency of the rudder. Under the impression however that a contrary result takes place, it was the subject of Maudslay's patent of 1845, to put the propeller behind the stern-post, in the position usually occupied by the rudder, and to employ two rudders, placed beneath the stern quartermaster, a little in advance of the propeller. An important use to which screw-propellers have already been applied in a few instances, and for which it is highly probable that they may be extensively adopted, is as a mere auxiliary power, for occasional use during calms and contrary winds. We are pleased to state that the new American packet-ship called the Massachusetts, which brings mail from Liverpool to New York, is a sailing vessel, fitted with conveniences of a very superior order, is provided with a small Ericsson propeller, 94 feet in diameter, and has towards the stern of the vessel a steam-engine which can be set to work when required, of 170 horse-power, capable of producing a speed of about 9 miles per hour in smooth water. The propeller is so constructed as to be raised out of the water when not in use. In sailing from Liverpool to America this vessel was kept in about 25 degrees of latitude, and between November 22 and November 18, 1845, gained from five to thirteen days as compared with five other ships which sailed either on the same or on the following day. The cost of the motive power in this vessel was about two-sevenths of her total cost, which was about $16,000. In a similar way an auxiliary screw-propeller is ordered to be fitted to the Ambigean frigate, which was launched at Woolwich in January, 1846, and which, though she is to be furnished with a screw of 16 feet diameter, and engines of 300 horse-power, which will render her quite efficient as a steam-vessel, has been built as a sailing ship, her construction having been commenced as long since as 1830.

We believe it will be generally approved by the British navy with her machinery entirely below the water-line, as in the American frigate Princeton.

Those desirous of investigating the history of screw-proellers, will find a full account of the invention in the report of the discussion which we have quoted, an ample chronological list of patents and inventions relating to the subject, from 1727, about which time a plan for propelling vessels up a river by means of screw was contrived in France, by M. Duquet, to the year 1843, in the 'Mechanics Magazine,' vol. xxxix, p. 292, with addenda on pp. 340 and 360 of the same volume.

STEENHAMMER, A genus of plants belonging to the natural order Boraginaceae. The calyx is divided into 5 deep segments. The corolla bell-shaped, with a short cylindrical tube with 5 minute protruberances in its throat. The stamens protrude beyond the throat, the filaments elongated.

S. maritima, the only British species, differs but little from Lithospermum except in habit. It has a procumbent branched stem, ovate, acute leaves, with rough, hard dots, glabrous, thin, and glabrous, having a taste resembling oysters. The nuts are smooth. The flowers in racemes and of a purplish blue colour.

(Baldwin's Manual of British Botany.)

STELLA, JACQUES, was born at Lyon, in 1506; his father, Francois Stella, who was also a painter, died when he was only nine years old. Notwithstanding the early age at which he lost both his parents, his father, Stella is said by other masters. At the age of twenty he went to Italy, and at Florence he was employed by the Grand-Duke Cosmo II. to execute the decorations which were designed for the celebration of the marriage of Ferdinand II. Stella made many designs and painted several pictures for the grand-duke, who gave him apartments and allowed him a similar pension to that which he gave to Callot the engraver. After living seven years in Florence, Stella went to Rome, in 1626, and contracted a friendship with Poussin, of whom he became also an imitator.

While in Rome he was, by some treachery or misunderstanding, thrown into prison, and while in confinement he assumed himself with drawing on the wall, in cipher, the figure of the Virgin with the infant Jesus in her arms. A report of the excellence of the drawing reached the Cardinals-Bishop of Bologna, who went to see it, and from that time a lighted lamp was suspended over it and the prisoners performed their devotions before it. In 1634 Stella returned by Venice and Milan to France, with the intention of visiting Spain. At Milan they offered for sale the pictures which he had made in Italy; but the public were unimpressed with his work, and he was induced to go to Spain, which he visited, and where he had been invited by the king. Cardinal Richelieu however succeeded in persuading him to Paris, and he procured him apartments in the Louvre, with the title of painter-in-ordinary and an annual pension of 1000 francs. In 1644 he was decorated with the cross of St. Michel and was elevated to the rank of principal painter to the king. He died at Paris in 1657.
Stella remained an imitator of the style of Poussin, but he did not go beyond the drawing and colouring of Poussin, and on the latter aspect he exaggerated the defect of Poussin: many of his pictures are very red. He excelled in pastoral pieces, and his father was a painter in both the French and English schools, and his interest in architecture which he showed in several of his greater works. He etched five plates himself, which are very scarce, namely, the Descent from the Cross; a Madonna; a Saint George; a genre piece with infants dancing; and a landscape, supposed to be of the Palace of the Grand-Duke of Tuscany, of the date 1621, which is very rare. Many woodcuts, apparently by P. Maupin, are marked 'Stella fecit,' but this alludes to the design, not the woodcut.

(Fabri, Entr'actes, etc.; D'Argenville, Vies des Peintres, etc.; R. Damoiseau, Peintres-Graffeurs Francais.)

STENOBAURUS, a crested and Enemies of the genus of Passerine birds which is distributed throughout the world.

STENELYTRA (Insects), the third family of heteromorphous Coleoptera in the arrangement of Latreille. Helops, Platella, Deroma, and Odhnera are examples. They are not of the next contribution to the group, in which their antennae are thickened at their extremities. They live under the bark of old trees, or on leaves and flowers.

STERNBERGIA (Bromeliaceae), the generic name for a small family of plants, the species of which are found in the Northern Hemisphere.

STERNOPTYX, a genus of small flies belonging to the order Salmonidae, though very different in aspect from salmon or trout. They have very elevated and much compressed bodies. They live in the warmer regions of the Atlantic Ocean.

STEWING is a process in cookery by which meat or vegetables are made fit for food by immersion in water at a high temperature for a considerable period of time. It differs from boiling by the temperature of the water not being allowed to reach 212° Fahr., and by being continued for a longer time. The effect is that of very thoroughly softening the substance used and the retort to a great degree of the favour of the meat or of the spices added. These ends are accomplished by employing vessels with very closely fitting lids. The material of which these vessels are made is commonly of copper, in which case, the owner of the vessel, or the German enamelled stewpans, so safe, and so well suited, from the extreme nicety of the composition, resembling earthenware or china, with which they are lined, to all delicate composition of copper, is to be kept very clean, and the tinning always perfect. If this is rubbed off acid and acetic liquid forms poisonous compounds, which produce serious and occasionally fatal effects.

When several stews or dishes of vegetables are made at the same time, a bain-marie, or water-bath, is the best apparatus.

This is a flat vessel containing boiling water: all the stewpans are put into the water, which is to be kept always very hot, but it must not boil; the effect of this is to keep everything warm without altering either the quantity or the quality, particularly the quantity.

Gentle stewing is incompatibly the best—the meat is more tender, and the soup better flavoured. By quick and strong boiling the volatile and finest parts of the ingredients are evaporated, and fly off with the steam, and the coarser parts are rendered soluble: so you lose the good and gain the bad. The full flavour of the ingredients can only be extracted by long and slow simmering; during which, take care not to prevent evaporation by covering the pot as closely as possible. (C. S.)

STICTA. (Lam.)

STIEGLITZ, CHRISTIAN LUDWIG, was born December 12th, 1766, at Leipzig, in which city both his grandparents and father were persons of station, the former, who died in 1794, his father, in 1800. Having been appointed to the office of proconsul. Surrounded at home with objects of art, for his father possessed both a collection of pictures and a cabinet of medals and minerals. Steiglitz inherited from them almost in his childhood those tastes which so amictiously cultivated throughout life, although they were altogether remote from his other studies and occupations. Though he was not a pupil of his father's, he formed a high taste in art, and in 1777, and in 1784 that of doctor of laws, on which latter occasion he produced his dissertation 'De Caesaris sui us Feudalis Germanicum in Germaniae negotiis sit.' In the same year he was made a member of the G. W. Society, and in 1776 he published 'Wardburg,' a poem in eight cantos, which appears to have attracted so little notice, that though bibliography has preserved its title, the production itself has obtained no permanent record in literary history. He also published some tales of romance and chivalry; but it was in a very different field from that of the poet or novelist that he gained his reputation and rendered essential service to a branch of literature to which he contributed a great part of his leisure. As a revisor of the works of his fellow-countrymen and an opponent of the nonsensical writers in it than of those who practise the art. It was in 1786 that he appeared, though then anonymously, as an architectural writer, with his 'Versuch über die Baukunst.'

The other method of conveying German Wissenschaften' several essays and minor treatises on various subjects relative to the aesthetics of architecture and decoration, one or two of which appear to have been also published in the latter year. In 1790 he was elected a member of the Rathskollegium, or Council of Leipzig, he first brought out his 'History of the Architecture of the Antients' ('Geschichte der Baukunst der Alteren'); and immediately afterwards engaged in a work of compilation, the 'Encyclopaedia of Civil Architecture,' in five volumes, the first of which appeared in 1792, the last in 1798. In the interim he brought out a work upon Modern Gardening, which came to a very successful conclusion, and a continuation of it was published 'Artistiche Blatter' (1800), a collection of papers on Decoration. In 1804 he began to publish, under the title of 'Zeichnungen aus der Schulen Baukunst,' a series of engravings, plans, and elevations, intended as select specimens of modern architecture; but though it was exceedingly well-received—for not only did it come to a second edition, but there was also a French one—the choice compromised both his judgment and taste, the majority of the specimens partaking of that feeble and inaptness manner which had just before prevailed in this country; and a great many of the subjects were taken from English publications—those, for instance, of Adam and Pater, which were reprinted in Germany, and among others such examples as the Trinity House, London, and the County Hall at Chelmsford. How he could reconcile them with his own theoretical principles is difficult to understand.

Whether it was owing to his being satisfied with what he had then done for architecture, or afterwards disinterested with his last work, some years elapsed before he again published anything on the subject, turning in the interim to studies more profoundly archæological; the fruits of which were an essay on 'Medals and Collections of Coins,' 1809, a treatise on the 'Fignerae employed by the Artists of Antiquity,' 1818, and 'Archæologia Unterthannen,' 1820. In the same year with the last-mentioned publication came out his excellent work on 'Ancient or Medieval German Architecture' (Alte-Deutsche Baukunst), which contributed not a little to direct attention to and inspire taste for medieval art and its monuments which has since struck root and grown up in Germany. His next work was his 'Geschichte der Baukunst,' a valuable compendium of the history of architecture from the very earliest period, and which appeared in five volumes, the first edition of which appeared in 1827, and the second, a greatly enlarged one, in 1837. Contrary to the opinion of Hirt [Harr. P. C. S.], Stieglitz has not, in his 'History of German Architecture,' derived its principles and characteristics from an original construction of stone, and not of timber or wooden framing. The list of his literary labours is further extended by 'De Enth. der Familie der Romanen ins Altertum,' 1806, and his 'Beiträge zur Geschichte der Ausbildung der Baukunst,' 2 vols., 1848; and it would be prodigiously increased were it possible to enumerate...
all the various articles which he contributed to the *Imeresia,* the *Kunstblatt,* and other journals; and to Ezech and Grüber's Encyclopedia. After having held the office of president of the Academy of Leopoldstadt and other appointments connected with the town government, Stiglits retired from public duties in 1830, though he retained the title and distinction of proconsul; and in 1834 the *Jubilee* or fifteen anniversaries of the church was celebrated by his townsmen, and a silver medal was struck and presented to him on that occasion. He died July 17th, 1836.

In Fürsten's *Bauzeitung* for 1888 there is a portrait of Sigismund accompanied by a full memoir of him, which we have made use of for this article.

**STIGLMAYER, JOHANN BAPTIST**, the late distinguished director of the Royal Brass-foundry of Munich, was born October 18, 1791, at Fürstenfeldbruck, a small market-town near Munich, where his father carried on the business of a blacksmith. At Fürstenfeldbruck is an old foundry called by Ludwig the Strong, of Bavaria, in atonement for the basty execution of his innocent wife Mary of Brabant, in 1280.

This foundry, which had undergone various changes, and had been at various times extensively decorated, was the school and academy of the barefooted blacksmith's son, though in his time it was a military stable for foals (Militär-föhnhof).

It contained stucco decorations by E. Asam, frescoes by Appiani, statues by Roman Boos, and other works of the last century. This building, as already observed, was Stiglmayer's academy, and also the site of the library and Museum of a book of the natural history, which, with a cactehism and prayer-book, constituted the whole library of his father. These woodcuts and the decorations of the foundry were diligently copied by Stiglmayer, who, with great industry and many unhappiness (he was unable to go daily for milk), at length ventured to introduce himself to the superintendent of the establishment, Herr Pfeiffer, who had heard was not only himself a draftsman, but possessed considerable skill in the art of engraving, and, embodied his talent in some regular elementary instruction in design. After this he was placed by his parents with a goldsmith at Munich, of the name of Streisal, and he attended in the evening the daily school (Försternacht), in which he obtained the first prize for industry and good conduct, amounting to 100 florins (8 guineas), by which he attracted the notice of M. Leprévier, the director of the Bavarian mint, who from this time took much notice of Stiglmayer, procured him admission into the academy in 1810, and became in a manner his patron. From the date of his admission into the academy, he pursued the regular course of study requisite for a statuary and sculptor, and at the same time practised seal and medal engraving. He was very successful in 1814 in a medal with Von Langer, the director of the Academy, on one side, and Moses making the water flow from the rock on the other. In 1816 he was appointed engraver of the mint, and he was sent in 1819, at the king's expense, to Italy to complete his studies.

It was in Rome that Stiglmayer's great patron, Ludwig, the third of Bavaria (then crown prince), became cognizant of his high abilities, and appears himself to have directed Stiglmayer's attention principally to metal-foundling, in preparation for his own great undertaking already projected by himself. In reference to this future occupation Stiglmayer repaired to Naples to witness the casting of the bronze colonnade of Charles I., to be directed by Francesco Righetti and his son Luigi, from the model by Canova; the Italian sculptor's reserve and jealousy however rendered Stiglmayer's journey in vain as regarded its principal object; he did not allow him to see the casting. But he was fully represented; after his return, he undertook the considerable trouble he obtained permission to erect a small, square, and, having procured the assistance of Beccati, an experienced founder, then to be found in few if any casters of that city, of Engald, and the casting of several works himself. The first wholly failed, but the second, a cast from Thorwaldsen's bust of Ludwig I., then crown prince, was completely successful, so much so, that Thorwaldsen, Paruoli, and other sculptors, to give him this additional authority, supplied him with some banditti who robbed him even of his sketch-books. He returned to Munich in 1822, but was at this time employed chiefly in his capacity as engraver for the mint, and on some unimportant works of sculpture for the new Sculpure Gallery or Glyptothek then in progress. To the models of this time belong that in commemoration of the marriage of the Queen of Prussia, for the minister Von Zeuner, and the historical monument of Queen Elisa. These busts were those of King Maximilian I. and the Queen Theresa, Count Döring, the ministers Baron Von Zeuner, and Lerchenfeld, Bishop Stuhler, and others.

In 1825, the year of his death, Stiglmayer had the great series of metal castings, and from this time he was exclusively employed in founding the numerous monumental works which have been executed for Ludowig I., the present King of Bavaria, some of which have the most extensive castings of modern times. In order to be as well prepared as possible for his arduous task previous to casting any great monument, he visited Berlin in 1824, to witness the casting of Ranck's statue of Biber, by Reiniger, who showed him everything in his power. Stiglmayer's great activity commenced with the reign of Ludowig I., in 1826, in the foundry established and afterwards much enlarged by the king, expressly for his own numerous undertakings in that important branch of art; and he left many, and the most considerable still unfinished, at his death. He was created in 1839 Knight of the Bavarian order of St. Michael.

The following is a brief summary of his labours—from his own designs—the monument to the Brazilian children Juri and Isabella, and the reclining figure of the Friable Von Mannclil, in the cemetery at Munich; the monument of Maximilian II., Elector of Bavaria, designed by Liebermann, to the statue of Otto, king of Greece, from his mother Theresa, queen of Bavaria, at Aibling; after Schwantaler—the twelve colossal fire-guarded statues of the ancestors of the King of Bavaria, ten of which were executed for the front of the imperial palace; and the status of General Bekker for his monument in Munich; the colossal monumental figures of Jean Paul in Bayreuth, Mozart in Salzburg, the Margrave Frederic of Brandenburg in Erlangen, and the Grand Duke Ludwig of Wurttemburg, and the gilt bronze pieces of table-service, with designs from the Nibelungen and Amelungsen, for the crown-prince of Bavaria: after Thorwaldsen—the statue of Schiller at Stuttgart, and the colossal monument of the Elector Maximilian I. of Bavaria, at Munich; and, after Ranck, the monument of King Maximilian I. of Bavaria, before the theatre at Munich.

He executed also the following architectural casts from models made in the foundry, chiefly from the designs of Von Klenze; the obelisk, 100 Bavarian foot high, in commemoration of the 30,000 Bavarians who fell in the Russian campaign of Napoleon in 1812; the bronze gates of the Glyptothek and the Walhalla; and the monumental column at Giebach; the interior pediments of the Walhalla, with the northern deities; the gilded candelabra in the new throne-room in Munich; the monument to the brave Oberst von Langer, with four allegorical figures; and the urn and the tomb of King Maximilian in the royal vaults (Fürstenburg) at Munich, after a design by the architect Ziemba. Besides the above works, which are completed, are the following works in progress: the large statue of Ludwig II., in the foundry; the monument of Stiglmayer's death;—the colossal statue of Goethe, for Frankfurt, after the model by Schwindtaler; and from the model of the same sculptor, the enormous colossal figure of Bavaria, nearly sixty feet high, to be placed before the Bavarian temple of Fame, or Ruhmshalle (now in progress in the suburb of Munich, and which will be completed in 1850). It is the largest statue in the world, measuring, with its pedestal, eighty feet; also, by Schwantaler, the monument of the late Grand-Duke of Baden, with a pedestal and four allegorical figures of the four circles of the dukedom; and the statues of the goddesses of the Arts and Sciences in the new building of the University of Munich; and casts from Teisserin's models of the statues of Ferdinand, king of Naples, for Naples, and of Bolivar, for Bolivia, in South America.

On Stiglmayer's death no one undertook the task on which the statue of Goethe was cast by his nephew and assistant Ferdinand Miller. Stiglmayer had suffered from illness two years previous to his death, and many supposed it owing to the untimely death of his friend Engald. He died of cancer in the stomach, which Breslaü, the king's physician, had previously declared to be the cause of his illness. (Kunstblatt, 1844; Soell, *Bildende Kunst in München.* )
STIL, JOHN, the son of William Still, of Grantham, in Lincolnshire, was born in 1643, and became a student of Christ's College, Cambridge, where he took his degree as Master of Arts. In 1670 he was appointed Lady Margaret's Professor in the mathematical and mechanical sciences in Suffolk and Yorkshire, and was successively Master of St. John's and Trinity Colleges. In 1588 he was chosen proctor of the corporation; and, in 1592, he was raised to the bishopric of Lincoln, and held till his death in 1607. Bishop Still is said by Fuller to have been 'one of a venerable presence, no less famous for a preacher than a disputant. He left a large fortune, chiefly derived from leading disputes, and the judicious composition of sermons on the sea. The historians of the drama converse in believing he has been, in his youth, the author of a coarse but humorous play, which, till the recent discovery of Ralph Royster Doyster, was held to be the earliest extant work known in England by the name of a comedy. It is called, 'A right pithy, pleasant, and merie Comedie, intytuled, Grammer Gurnet's Needle: played on stage not long ago, in Christ's College in Cambridge.' Made by Mr. S., Master of Art, 1576. 'Gammer Gurton's Needle' is in Hawkins's 'Origins of the English Drama,' and in the second volume of Dodson's 'Mesters.'

STIPA, a genus of grasses belonging to the tribe Stipeae. It has stalked flowers, the pale coriaceous, the inner entire. S. pumila, the only British species, has a very long twisted feathery awn, with a glorious base. It is a very beautiful plant on paper, or our gardens. Found on rocks in Long Seadae near Kendal. (Babington. Manual of British Botany.)

STOCKADE, in Fortification, is the name given to a wall constructed a certain generality by piling together the exposed trunks of trees, or rough piles of timber, so as to inclose an area which is to be defended. The trunks or piles are planted close together; and at intervals of three feet from one another loopholes are cut through them, or notches a few inches long are cut down, vertically, from the top, through which the defenders may direct a fire of musketry on the assailants. An inclosure of timber so planted is sometimes called a Pullaska, from a name which is said to have been given by the Poles when they first entered Europe, to their field-redoubts or small entrenched camps.

Stockades are still frequently constructed as temporary fortifications in countries which abound with timber, as in North America and the East Indies; and, among uncivilized nations, as the Patagonians of Patagonia, are the only kinds of fortification which have been executed. They were also, in general, the means employed by ancient armies while besieging towns, to protect themselves or to prevent the escape of the garrison. The walls with which the Peloponnesians surrounded the besieged thebes and the agis had on one of those walls were stockades of timbers, and palisades planted closer together in a double line with a certain interval between the lines (Theophrastus, ii. 76); and the fortresses of the Drile, a people of Habas, which are on the Eastern Sea, are described by Xenophon (Anab. ii. 2) as strong palisades, with a space between the state inclosure and embankment, on the latter of which were palisades and wooden towers. The description of the Pahn, or Hippahs, of New Zealand, which is given in the accounts of Captain Cook's voyages, would nearly serve for the stockades within which the natives of that country very recently resisted the assault of a British force. It is stated that the works consisted of trunks of trees planted close together, with a small inclination towards the interior space; and that at intervals from one another, particularly at the angles of the works, there were loopholes for the musketry of men who had mounted behind them. As these loopholes were covered with a slanting of the top of the wall, so that the defenders were able to see the ground at the foot of the wall while they were concealed from the view of the enemy. In the interior there was usually a high mound, so that in cases of attack or inspection, the pales and palisades, were deposited. The pales are generally on the summits of heights, and they are sometimes strengthened by outworks of a similar nature.

STO Fac for BUILDING. In the United States of North America, during a war, stockades consisting of roughly-hewn trunks of trees planted close together in upright positions and pierced with loopholes for musketry, are very frequently constructed for the purpose of protection from the fire of the enemy, and at each of the angles of the inclosure a sort of blockhouse, serving as a bastion to flank the stockade, is constructed with very thick logs of timber placed horizontally.

These block-houses are sometimes formed with an upper story, the angles of which project over the sides of the lower one, so that by loop-holes in the projecting part of the floor a fire of musketry may be made upon the enemy when at the foot of the wall.

STOCKINGS, [WEAVING, F. C.] STONE for BUILDING. The durability of stone may be examined in several ways, and results of much importance to this in the area of shingles is obtained by some latter investigations at the foot of the purpose for determining on a proper stone with which to construct the New Houses of Parliament. In their natural repositories the surfaces of rocks are exposed to the action of the atmosphere and mechanical agencies connected with the atmosphere and dependent on the climate. Rocks which are composed in any considerable degree of carbonate of lime or carbonate of magnesia— or which contain minerals into whose composition silicates of iron or of the acid silicates are transferred to buildings in great towns, the air, loaded with sulphurous and other acrid vapours, is still less favourable to their preservation.

Not only the freely consolidated chalky rocks (like that of Mortemer), but the more solid Cotyles of Bath and Portland, have failed to withstand the injurious action of the atmosphere; nor is even the finest mountain limestone of Derbyshire or half-crystallized and half-cordifoliate marble of Plymouth capable of preserving its edges and angles from slow decay and efflorescence, even in a country so dry as that of the Cotyles or the comparatively low and tranquil regions of Devonshire. Even the purest crystallized marbles of Attica or Carrara, which may endure in the sunny regions of their birth, cannot be kept without injury to the moist and variable climate of Britain.

If, desiring to find a perfectly durable limestone, we turn our attention to other classes of rocks, we find other causes of decay equally influential on them, and a large proportion of these is the class of sandstones which comprises every degree of bad quality, but scarcely the highest degree of good—the imperceptibly decaying nullite gneiss of the Drudillar hills at Borrowbridge. When we consult the map, we are enabled to trace the original出产 to which the architectural beauties of Carlisle, Chester, and Coventry have been unfortunately trusted. Granite scarcely merits universally, nor even generally, the reputation of a very durable stone in Britain. Some of the Cornish and Devonian granite is of little permanence, much of that in Cumberland and the island of Arran is quite perishable, nor is all the stone of Killiney, near Dublin, free from the same reproach.

The decay of granite is usually ascribable to the unequal action of the atmosphere on its dissimilar and unequally resisting ingredients. The felspar often decays through the chemical action on the surface, and the quartz at the bottom of the rock, and the same may be said of the layers of granite and slate which alternate as cold wet and dry, alternate wetness and dryness, sunshine and shade, complete the disintegration. Similar remarks apply to many sandstones, for these often contain disintethrown felspar, granitic, and metallic, more or less mingled with the quartz, which is compacted with the quartz and mica of granite. The arenaceous rocks however yield with too much facility to the hygroscopic and other changes of the atmosphere, and except we can obtain almost pure quartz sandstones with almost confluent grains we cannot be confident of their durability. Now, such sandstones, like the harder granites, are unfitted for architecture, however useful for walls, paving, and other rough purposes.

STONE for BUILDING must in general be freestone firm enough to sustain great pressure, and yet so aggregated as to admit of easy working from facility by ordinary tools, and of receiving correct surfaces in any direction. It must in general yield masses of great dimensions. Its colour is of consequence to the architect, who is necessarily attentive to this element of effect; and the colour which belongs to the stone is very often, indeed generally, modified in buildings by the growth of lichen, the access of moisture, and the change of oxidation of the contained iron. By so many considerations, and the above limitations, it is evident that, in very few samples can be really placed in competition.

In the great variety of limestones and sandstones which are adapted for building purposes, we remark, by the aid of the microscope, the difference in the constitution of molecular aggregation: mixtures of grains; segregated concritions of grains; and compacted crystallizations.

To give an idea of the applicability of this classification, we
may shortly review a small series of examples of limestones arranged in a geological sequence. None are mentioned except such as have been tolerably well exposed. The
which are not really freestone or which have not been found
are inclosed in parentheses.

**Geological spec.**

**Sandstones.**

**Callozoic.**

Sarsen stone used in Sodbury. A mixed mass. It hardens on the surface by exposure.

**Mesozoic.**

(The freestone of Sodbury; a mixed mass. It has decayed in the churches of Sodbury.)

The 'calcaeous grit,' as it is called, of Yorkshire. It is a mixed mass (with little or no carbonate of lime). It is used at Duncombe Park; hardens by exposure.

The 'Kelloway' rock of Yorkshire: a soft mixed mass, very slightly cemented, hardens by exposure. Durable in the vicinity of Hackness.

The ferruginous sandstone of the inferior oolite: a mixed mass; is much used in the Midland Counties, and is often found in old churches well preserved, e. g. Northamptonshire.

The new red-sandstone of Penrith, mixed, durable in the old Castle; Giant's grave &c. (Other specimens of finer grain are among the worst stones of the kingdom.) A light coloured sort, called 'Keeper,' quarried near the Mavern Hills, is durable.

**Paleozoic.**

(Few of the sandstones of the coal-formation are of much durability, though many are of great beauty.) In the lowest part of the coal strata are good firm, rather coarse-grained, mixtures, as near Leeds: and below these the well known millstone-grit, the base of the northern coal-fields. This stone was used by the Britons and Romans in the north of England. In the natural rocks of Brin- ham, the Devil's Arrows of Borrowbridge, and the abbeys of Kirkstall and Fountains, it has not well resisted the atmosphere; but its decay is slow.

The magnesium limestone, a crystallized mass, varies in its compactness. It varies also in texture, from a confused aggregation of crystallized grains, to a small cellular texture, the walls of the cells being composed of small crystals; and finally to a largely cellular mass, the interstices of the cells being either compactly crystallized or filled with a soft earthy mass. In fine examples of this stone, as those of Mansfield, Boleover, Anston, Roche, and Huddersfield, the chemical constitution is nearly the same (one atom of carbonate of lime to one atom of carbonate of magnesia), and it is in the mode of aggregation that we are to seek the explanation of the very superior durability of these to nearly all the other magnesian limestones.

The thick beds of the mountain-limestone are often a mix for building, but seldom very tractable in ornamental work, except when the marly-seam area adopted or imitated. It is one of the characteristic limestones of limestones, though, generally only a mixture of grains. The fragment of the limestone is generally durable, but particular cases of failure occur. Stones of nearly corresponding age and of great durability have been much quarried near Barnard Castle and Bowes.

In considering even the few cases here adduced, we find mixed, concretionary, and crystalline textures, some of which are durable, others perishing. Mixtures of very similar or very dissimilar parts, as millstone-grit; concretions which have earthy textures in their interstices, as some oolitic limestone; crystallizations which do not produce compactness, in some magnesian limestones; and particularly in the sandstones mixtures, as the Sarsen sandstone, the Craigleith sandstone, and some mountain-limestones; concretions of adherent globules, as the oolite of Kettlet; concretions of globules cemented by sparry interstices, as the oolite of Aneur; and crystallizations with uniformly adherent grains, as in the magnesian limestone of Bolsover,—these appear to be durable. The microscope may determine in many cases between one class and the other. Additional evidence may be obtained by exposing masses of stone to frost and sunshine, rain and wind, to imbibition of salts which expand in crystallisation, and to mechanical pressure. And there remains one further class of evidence more important than all the rest—and that is experience. By observing how the various sandstones and limestone stones have behaved in castles and abbeys, and churches, we may attain with the highest probability a correct estimate of their intrinsic durability.

The commissioners (Mr. Barry, Sir H. De la Beche, and Dr. W. Smith) who reported on the choice of stone for the construction of the New Houses of Parliament, have neglected none of these considerations, and their report, certainly the most valuable document which has ever appeared on this subject, embodies a great mass of valuable statistical information on the most famous quarries; accurate notices of the most remarkable buildings which were constructed from them; and chemical analyses and mechanical experiments on the stone. The strength of several sorts of stone, as measured by the weight necessary to be applied for breaking and crushing them, appears below:

The asterisk is placed to two numbers. One refers to the sandstone of Darley Dale, which bore the greatest weight previous to the first fracture, and the other to the Kettlet rag, which bore the greatest weight before crushing (this can hardly be an average specimen of the stone). Of sixteen specimens selected, the stone most absorbent of water was...
proved to be the Bath colite from Box; that most in-
herited by Brard's artificial process of disintegration was the
Barnack stone: and that which was most easily crushed was
there may be of service in the description of the stone. Stanes were
least absorbent, magnesian limestones least disintegrate-
magnesian limestones (as that of Bolsover, finally recommended
were almost as little porous. (Report of the Commiss-
uncommonly decay by disintegration at the surface, losing grain by grain in proportion to time and ex-
posure. But they sometimes suffer a singular change, as if both birth; and that part of the natural enveloping crust is thus
formed, as at Stonehenge, where the interior is soft, but the
exterterior hard. This process appears to render such a stone
durable. But if carried further, so as to produce a new tex-
ture of the surface, the external shell separates from the in-
terior mass, decompounds and falls off, leaving a rough soft
inner core. This happens even to moulded surfaces like those
of balusters. Stones composed of parts unequally mixed suffer
unequal waste in different parts. Shells, corals, concretions,
and crystallized masses, thus appear prominent from early
limestones, and indicate the general fact that, in proportion
the force of molecular aggregation in the stone, is the re-
sulting durability of the stone.
Again, the circumstances under which a stone is exposed in
a building influence its conservation. It is not the amount but
the kind of exposure which governs its decay. The southern
and eastern sides of the Art of Painting monoliths from
southern and eastern resist. Prominent cornices often are perfect,
while below them the mouldings are reduced to shreds.
The drip-mouldings remains and is even hardened, while the parts
which it has impregnated and protected have been moulded away.
Moreover, the Incised surface has actually occurred to the observation of the writer in the
space of only a few years. In fact since 1839 the same
pieces of magnesian limestone remain perfect in the drip-
mouldings, while the notice of the whole ornamented
surface below is ruinously decayed.
STONE, NICHOLAS, master mason to Charles I., was
born at Woodbury, near Exeter, in 1586. He lived three years
in London with one Isaac Jones, his master, and then went
to Holland, where he worked for Peter de Reyser,
whose daughter he married. He returned to England about
1614, and was for many years chiefly employed in making
monuments for the nobility and gentry. In 1619, he was
appointed master mason for building the new Banqueting
House of Whitehall, on which he was engaged two years at
4 shillings and 10 pence per day; and in 1626, at the com-
mencement of which work, he obtained a copy of the
master masons of Windsor Castle. The patent is in
Hymer's 'Fodera,' vol. xvii. p. 675. The history of Stone's works
is fully recorded by himself in a pocket-book, which was in
the possession of Hawkins, and now in the possession of
Vereker, from whom he obtained a copy. This pocket-book contained a full account of
the various monuments he had executed, with the sums of
money he received for them, and the names of the persons
for whom they were constructed.
According to this book, Stone erected in 1624 a monument
to the Earl of Ormonde, at Kilkenny, for which he received
400l. He received in the following year 600l. for a monument
to Henry Howard, earl of Northampton, erected in Dover
Castle. For a tomb made for lady Harrington, Countess of
Bedford, 1616, he bargained for 1020l., besides the charges
for carriage and iron and setting up. This year he went to
Scotland, and he gives the following account of his trans-
actions there:—July, 1616, was I sent to Scotland, where I
undertook to do work in the King's Chapple and for the
King's Closest, and the organ, so much as came to 430l. of
gainson works, the which I performed and had my money
well paid, and 50l. was given to drink, whereof I had 20l.
given me by the king's command. He mentions drink-
money on other occasions. Stone made several monuments for
Charles I., and received 60l. for each one, and another 16l. to Spencer, the
post, for which the Countess of Dorset paid him 40l.
In 1625, he made for the old Exchange of London four
statues—Edward V., Richard III., Henry VII., and Queen
Elizabeth; and was paid 400l. for such works. For the three kings he received 25l. each, for the queen,
30l.; 25l. appears to have been Stone's ordinary charge for
a statue, including the pedestal.

Stone received altogether nearly 12,000l. for the various
monuments erected by him. The various sums for monu-
ments noted in his pocket-book, amount altogether, ac-
cording to his book, to 12,300l. Besides this, he acquired his information concerning Stone's family, to 10,882l.
Walpole has given a list of the principal monuments, and
mentions some architectural works by Stone. He died
August 24, 1645, and was buried in the church of the
Martin's Church, where there is a slab to his memory with an inscrip-
tion and his profile. His wife and his son Nicholas are
buried in the same grave: they both died in the same year a few months after his death. Stone had three sons, Henry,
Nicholas, and John.

Henry Stone, known as Old Stone, probably because he
was the eldest, was a stonemason and painter, but he was chiefly
engaged in painting monuments, and studied in Italy and the Netherlands,
and made many excellent copies of celebrated Italian and Flem-
ishing pictures: there is a large copy at Hampton Court of the
celebrated picture, by Titian, of the Comaro Family, now in
the possession of the Duke of Northumberland. He lived in
Long Acre in the same house that was his father's, which he
rented of the crown for 10l. per annum. He died in 1653,
and was buried near his father; and the following inscription
in his memory was placed in the church by his brother John:

"To the memory of Henry Stone of Long Acre, painter and
statuary, who, having passed the greatest part of thirty-seven
years in Holland, France, and Italy, achieved a fair renown
for his excellence in arts and letters, and in the decline of his
life on the 24th day of August, A.D. 1653, and lyeth buried
near the pulpit in this church." Here follows some laudatory
verses. Old Stone wrote a book, entitled the 'Third Part of
the Art of Painting,' written in Latin, and sent to one
who saw this book, was uncertain whether the two former
parts were composed by Stone, or by some other author.

Nicholas Stone, the second son, who was a stonemason,
also studied abroad and made excellent copies of celeb-
rated works. Mr. Bird, the stonemason, says Walpole, had the
't Lascooun' and Bernini's 'Apollo and Daphne' in	terra-cotta
duly authenticated.
Him. He returned to England in 1642, and died in the
same year as his father, as noticed above. Venetius saw a
book of drawings by him of many buildings in Italy.

John Stone, the youngest, was also a stonemason, though he
was originally designed for the church, and was educated at
Oxford. In the civil war he entered the King's army, and
narrowly escaped being taken. He concealed himself for a
year in his father's house without his father's knowledge, and
at length contrived to escape to France, where he probably
took to the arts, as he was afterwards, noticed, and in the
life on the 24th day of August, A.D. 1653, and lyeth buried
near the pulpit in this church." Here follows some laudatory
verses. Old Stone wrote a book, entitled the 'Third Part of
the Art of Painting,' written in Latin, and sent to one
who saw this book, was uncertain whether the two former
parts were composed by Stone, or by some other author.

Nicholas Stone, the second son, who was a stonemason,
also studied abroad and made excellent copies of celeb-
rated works. Mr. Bird, the stonemason, says WALPOLE, had the
't Lascooun' and Bernini's 'Apollo and Daphne' in terra-cotta
by him. He returned to England in 1642, and died in the
same year as his father, as noticed above. Venetius saw a
book of drawings by him of many buildings in Italy.

STOWELL, WILLIAM SCOTT, BARON, was the elder brother of Lord Chancellor Eldon, and the eldest son of Mr. William Scott, coiffleur, of Newcastle, by his second wife, Jane, daughter of Mr. Henry Atkinson, who was of the same profession. [Exon, Earl of C.S.] He was born on the 17th of October, 1748 (O.S.) at Heworth, a village on the Tyne, about three miles below Newcas-

tle, and a considerable distance from Durham, to which his mother had been born a few days before, in the apprehension excited by the advance of the Scotch rebel army after the battle of Prestonpans. Egress in any common way being imprac-
tical, he was smuggled away, disguised to be a sort of basket over the town wall, which ran along the quay, separating Mr. Scott’s house in Love Lane from the river, where a boat was in readiness to receive him. At Heworth she and her sister, Jane, and a daughter, who was named Barbara and died in infancy.

William was educated with his two younger brothers, Henry and John, at the Royal Grammar-school of Newcastle, under the Reverend Hugh Moises. Moises is said to have been principally instrumental in getting both William and John

sent to college. William entered the University of Oxford in February, 1761, standing for and obtaining a scholarship at Corpus Christi College; but he had not long continued there when he

was told that he was required to go home. It is remarkable that for his eligibility on this occasion likewise he was again indebted to the accident of his being a native of Durham. He was now also elected by the same society a College tutor in the same capacity previously occupied by Dr. Scott. William (afterwards Sir William) Jones, who had recently left Oxford for the metropolis. In 1767 he took his master’s degree; and in May, 1772, he proceeded B.C.L., having been elected by this society in the same capacity as an advocate at Doctors’ Commons. He had already, with a view to the study of the law, entered himself at the Middle Temple, in June, 1762. He was detained at the University however a few years longer than he otherwise would have been by being elected in 1774 by the members of convocation after a contest, to the office of Camden Reader of Antient History. The lectures which he delivered in this capacity attracted crowded audiences, and brought him into high and wide reputation. It is said that they still exist in manuscript.

At last, in 1778, he retired from the office of College tutor; but he still continued to reside in Oxford till the following year, when he had taken his degree of D.C.L., which he did in 1770. On this occasion, in the University church, he went out grand compourner, which meant that he paid the higher fees ex-

pected of members of the degree. He had saved money from his income as Fellow, and his constantly increasing receipts during the twelve years that he held the office of College tutor; but it is to be remembered that he also had inherited a considerable property, and that he was one of the richest men in Oxford, who died in 1776. It was probably the independence to which he was thus raised that determined him to resign his employment as a college tutor; but it appears that old Mr. Scott’s son was not the only one who, according to Mr. Twiss, was to be by Mr. Twiss in the first and second editions of his Life of Lord Eldon. He left somewhat less than 20,000l.

He now entered at Doctors’ Commons, and passed another year partly in Oxford, partly in London, the rule being that no one shall practise as an advocate till the expiry of that space of time after his admission, which according is called his year of silence. Dr. Scott was called to the bar in February, 1780. He was admitted into the Faculty of Advocates at Doctors’ Commons, according to Mr. Surtees in one place in November, 1779, in another place not till the spring of 1780 (Sketch, pp. 36 and 81). So early however as December 1777 he had been elected a member of the famous Literary Club, having been mainly indebted for that distinction to the favour of Dr. Johnson, to whom he had been introduced in University College by their common friend Chalmers. At this time he was at the University of Edinburgh. He soon became a favourite with Johnson, whom he had

accompanied from Newcastle to Edinburgh, when the latter set out on his tour to the Hebrides, in the autumn of 1777. With the introduction of Johnson’s' qualities, Scott rapidly made his way to distinction in the most intellectual society of the English capital.

His talents and learning, and the reputation he had brought from the University, brought him a large practice in his profession from his first entrance upon it. And his success as an Advocate in no long time led to promotion. In 1783 he was appointed to the office of Registrar of the Court of Faculties. In 1788 the Bishop of London appointed him Judge of the Consistory Court; and the Archbishop of Canterbury, his Vicar-General, or Official Principal. In the same year he was made Advocates-General, and knighted, and was also nominated a Privy Councillor. In 1790 he was nominated by the archbishop Master of the Faculties. Fi-

nally, in 1798, he was made Judge of the High Court of Admiralty.

Meanwhile, after having in 1780 been disappointed in his expectation of being sent into parliament as representative of the University of Oxford, and having been unseated on a motion in 1764, when he had been returned for Dover, he had been made a second time returned for that borough, in 1780, through the influence of ministers with the patron, the Earl of Radnor. He was again returned for Dover to the next parliament, which met in 1786. At last in March, 1801, on a vacancy occurring by the retirement
of Francis Pag, Esq., he obtained the object of his early ambition by being elected member for his University; and that seat he retained as long as he continued a commoner.

The manner in which this object was first secured, and by numbers of works which have been raised to the perusal in 1805; but some unexplained court intrigue interfered, and he was not ennobled till the 25th of July, 1821, when he was created Baron Stowell, of Stowell-park, in the county of Suffolk, by the late Lord Melbourne, in the ninety-second year of his age. For the two last years of his life he was reduced to a state of mental imbecility; and he died at his seat of Early Court, Berks, after an illness of a few days, on the afternoon of Thursday, the 25th of October, 1836, in his ninety-second year. He had been twice married; first, in April, 1811, to Anna Maria, eldest daughter and co-heiress of John Bagnall, of Early Court, in the county of Berks, Esq., who died in September, 1811, and the 9th of April, 1812, to Louisa Katherine, Marchioness Dowager of Sligo (widow of the first Marquis and daughter of Earl Howe), his acquaintance with whom had originated, singularly enough, in the circumstance of his having preceded in the preceding December at the Admiralty Sessions at the Old Bailey, on the trial of her son, the late Lord Sligo, for inveigling some seamen from one of the king's ships to serve on board his yacht (for which he was sentenced to pay a fine of 500l., and to be imprisoned four months in Newgate). This last proved a very unsatisfactory connection; but the lady died in August, 1817. By his first wife Lord Stowell, besides a daughter who died in infancy, had two sons, Sir J. G. and Lord Stowell, both of whom died in infancy. Secondly, of the late Viscount Sidmouth, a son, William, who died at the age of forty-two, about two months before the death of his father, was born, is the highest English authority in his own department of the law, including both ecclesiastical law and the law of nations, if not the highest of all authorities upon the particular questions which he had occasion to consider and decide; for, having produced no complete treatise upon either of the branches of jurisprudence which he administered, he must be distinguished from the great text-writers, between whom and him no comparison is properly admissible. His judgments in the court of admiralty have been reported with precision and carefulness by Lady Haggard and Phillimore; those delivered by him in the Court of Admiralty, in an equally superior manner, and, in part, with the advantages of his own revision, by Drs. Robinson, Edwards, Dideon, and Haggard. Their characteristics are the most complete mastery of all the learning of his subject, great comprehensiveness of view, a penetrating sagacity in the disentanglement of the essential points and governing principle of a case from the confusion and sometimes apparent contradiction of details and accessory circumstances, a remarkable faculty of luminous and striking illustration, and all this combined and set off with a diction graceful and elegantly expressive, though occasionally somewhat diffuse and rhetorical. Some of Lord Stowell's judgments may be called almost revelations of the law, being exposures of large and intricate questions which had been long the subject of much discussion, but which he has completely cleared up and set at rest.

As a politician this distinguished lawyer was, like his brother, Lord Eldon, an uncompromising Conservative, shrinking from all change as only the beginning of universal ruin. Except, however, by giving his steady vote in support of his party and his principles, he very rarely took part in the proceedings of either House of parliament. During the first six years that he sat in the House of Commons, he only spoke once; of some two or three displays which he afterwards made, a speech of three hours' length, which he delivered on the 7th of April, 1802, on moving for leave to bring in a bill for amending the statute of 21st of Henry VIII., respecting the non-residence of the clergy, was the most memorable. He was also instrumental, however, in carrying through the House several other measures having a reference to the established church, of which he was the supporter on all occasions, considering himself indeed as a sort of representative of the clergy, both in his quality of member for the University of Oxford, and from his office as an ecclesiastical judge.

STROPHIOTES, a genus of endogenous plants belonging to the natural order Hydrocharidaceae. It has a 3-parted calyx and 3 petals. The male flower has 12 or more stamens surrounding the ovary. The plant is a small to medium-sized aquatic plant, with floating leaves and flowers. The fruit is a capsule, containing numerous seeds.

STREPTOCYCLIS, a Water-soldier, has sword-shaped triangular leaves and a rosette of floating leaves. The plant grows in mud, and sends out rigid leaves like those of an aloe. The stalk is compressed, 5 or 6 inches high, with two leaves near its summit. The flower is white and delicate. It is a very ornamental aquatic plant, and is found in ditches in the east of England. It remains under water during the greater part of the year, but raises itself to the surface on special occasions during the season for fortifying the seeds.

STREPTOSPERMA, a very extraordinary order of insects, remarkable for having the anterior wings transformed into a pair of short, slender, comforted appendages, whilst the posterior are very large and fold in the manner of a fan. The mouth is armed with two slender acute jaws and two pointed palpi. The tarsi are 2- or 4-jointed. The larva is vermiform and has no feet. The pupae are inactive. They are all very small creatures, the largest not so long as a quarter of an inch thick. The larvae live on leaves of grasses and mosses; the perfect insects are very short-lived, but very active.

These insects are the Rhipiptera of Laënnec, the Diptera Rhipiptera of Wernicke. Their systematic position has been much debated.

They were first observed by Mr. Kirby, who gives the following account of his discovery:—"Observing scars-like impressions on animal infesting the abdomen of various Andreae, he attempted to remove one, and to his surprise drew from the body of the bee a white fleshy larva a quarter of an inch long, the head of which he had mistaken for an ear. 'How the animal receives its nourishment after the removal of its head is a singular creature. 'When I had examined the head under a strong magnifier, I could not discover any mouth or proboscis with which it might perforate the corneous covering of the abdomen, and so support itself by suction; on the under side of the head, at its juncture with the body, there was a concavity; but I could observe nothing in this but a uniform unbroken surface. As the body of the animal is inserted in the body of the bee, does that part receive its nutrition from it by absorption? After I had examined one specimen, I attempted to extract a second; and the reader may imagine how greatly my astonishment was increased when, after I had drawn it out a little way, I saw its laevity of form and the fibres of the antennae and antenna consisting of two branches, break forth and move itself briskly from side to side. It looked like a little loop of darkness just emerging from the infernal regions. I was impatient to become master of its habits, and the insect, having been made a species of the genus, whose very class seemed dubious. ' (Monographia Apicis Angllicae, vol. ii. p. 111.)" 

Stylurus and Xeno are the genera of this order. For full information consult the writings of Kirby, Curtis, and Westwood.

STIGMOCETHALUS, a genus of fossil Brachiopoda from the Devonian strata of Plymouth, the Eifel, &c. (De- rivation).

STROBILITES, a genus of fossil fruits from the Cretaceous and Oolitic strata of England. (Lindley.)

STROMATOPORA, a fossil genus of corals from the Silurian and Devonian strata. (Goldfuss.)

STROMBODES, a fossil genus of corals from the Silurian, Devonian, and Carboniferous limestones. (Schinz.)

STROPHODUS, a genus of fossil fishes, including many species from the Oolitic and Cretaceous strata of England. (Agassiz.)

STUERBOUT, DIERICK, commonly called DIRK VAN HAARLEM, was born at Haarlem, in the early part of the fifteenth century. He is perhaps the oldest of the Dutch painters, and one of the best of the early masters. The two large works by him in the Royal collection at the Hague are wonderful works for their time, and, independent
of their age, are two of the most interesting pictures in the European collections. They were at one time attributed to Mengs, whose works they somewhat resemble; their history is well known, and their making is mentioned in some Ms. Annals and Antiquities of Louvain discovered by M. de Bast. The pictures were preserved at Louvain until 1827. They were bought by the Duke of Beaufort, and placed him in the catalogue of the gallery of the King of Holland, the first and second pictures of the Emperor Otho and the Empress Mary. Their subject is from a story of the old chronicles of Louvain, called the Galerie des Vaisseaux. The event took place in 1265. The Emperor Otho III., on his return from a journey to Rome, was condemned at Modena one of his courtiers, an Italian count, to death, in consequence of an accusation from the empress (Eliane de Luid), that he had attempted her honour. His count was beheaded, but immediately afterwards his widow, with his head on one arm and a red-hot iron which she holds with impunity in her other hand (an infallible proof of her husband's innocence), on her knees supplicates the emperor for justice. The emperor, being convinced by the fire ordeal of the count's innocence, orders the empress to be burnt at the stake.

From this tradition Steuber painted two pictures for the Town-hall of Louvain in 1468, on wood, each 117 inches French, by 66; the figures are about the size of life. In the first picture the emperor is listening to the false accusation of his count; in the second, the count is being executed; the actual beheading is represented in the distance. In the second picture the widow is kneeling before the emperor with the head of her husband and the red-hot iron in her hand, imploring the imperial intercession for the empresse. She is being burnt at the stake; in both pictures are various attendants. The execution is in the style of the Van Eyck school, and is extremely elaborate, especially in the second piece, which is superior to the first.

These pictures were fixed on the wainscoting of the justice-hall at Louvain, and by each was a panel containing an explanation of the subjects in the Flemish language, and in gold Gothic letters. They were very dirty, and fast approaching decay, when in 1827 they were purchased for a small sum by the late King of Holland, who presented them to the present king, then Prince of Orange. They were removed to and restored at Brussels, and were in the collection of the Prince of Orange there, until 1841, when they were placed in their present locality at the Hague.

In the above-mentioned MS. 'Annales et Antiquités de Louvain,' it is stated that Dierick Steuber painted these two pictures for the Council-hall in 1468, and that he was paid for them 280 crowns. In the same MS. it is stated that the middle of the 24th of May 1693, the same Dierick Van Harem, though that writer mentions them as two painters. Vasari mentions Dirie da Luvano. Steuber must have resided some time at Louvain. He was also from his style probably a pupil of Jan Provoost, and in some points of his art was equal to that artist. These two short extracts from the pictures prove that Steuber was a much better painter than many of the most celebrated of his followers; the proportions of his figures are better, his forms fuller and better modelled, and the heads are executed with less rigidity and stiffness of feature. M. Nieuwenhuyx and others give 1410 and 1470 as the respective dates of Steuber's birth and death, but how the information is acquired is not stated; Van Mander, who published in 1604, said nothing either. They appear to have originated with Otley, who makes some conjectures on the matter in his 'Early History of Engraving.'

(S.B., Messager des Sciences et des Arts, Ghent, 1833.)

 subsystem: [P. C. S.]

SUBLEYRAS, PIERRE, a distinguished French painter, was born at Uzes in 1699. His father, who was also a painter, was his first instructor, but at the age of fifteen he took his uncle in Paris, who in 1716 placed him in the studio of Boulanger, a painter of reputation in that part of France. In 1724 he went to Paris, and two years afterwards obtained the grand prize for painting given by the French Academy for a picture representing the death of St. John of Nepomuk. On his return to Rome, with a pension from the then government, and he remained there the remainder of his life, and acquired a great reputation. In 1789 he married a Roman lady, Maria Féliz Tiabin. On his death he left an unfinished picture which was bought a short time afterwards elected members of the academy of St. Luke. Subleyras was patronized by the popes Clement XII. and Benedict XIV., by several cardinals, and many of the Roman nobility. He painted Benedict's portrait, and was commanded by that pope to execute one of the altarpieces for St. Peters, to be worked in mosaic. The picture, representing St. Basil celebrating mass before the Emperor Valens, who is seated with a fasting fit, was finished in 1746, and after being exposed in St. Peter's for three weeks, was removed to the mosaic offices, and completed in mosaic before the death of Subleyras. He died at Rome of pulmonary consumption in 1757, and is buried in the church of St. Peter in Rome.

There are several fine pictures by Subleyras in Rome and in some other cities of Italy, and a few in France: there are eight in the Louvre. His execution was delicate, but he composed his pictures with too much a direct study of the Tintoret. His figures are larger in his oil pictures than in his altarpieces; among these three of the pictures which are in the Louvre—the Brazen Serpent, Mary Magdalen at the feet of Christ, and St. Brigid, restoring an infant to life. There is also a Holy Family by him.

(D'Argenville, Abrégé de la Vie des Peintres, &c.; B. Dumontel, Peintre-Grauvier Françoise.)

SUBULARIA (from subul-, a little sword, from the form of the leaves), a genus of plants belonging to the natural order Cresse- forme and the tribe Subulation. It has an oval-oblong, compressed pouch, with boat-shaped valves.

S. aquatica, S. awl-wort, is a little aquatic stemless herb, with fuscous, simple white fibrous roots. The radical leaves are linear and awl-shaped, the scape naked and flowerless, the pedicel filiform and bractless. It is native of the colder parts of Europe, in ditches, lakes, and ponds with muddy or gravelly bottom. It is also found plentifully in the north of England, Scotland, and Ireland. Sir W. Hooker and Sir J. E. Smith agree in stating that the flowers always remain several feet under water. No one is so far aware that, contrary to the general rule, fertilization must take place in that element. This curious little plant only requires to be planted or sown in a pond or rivulet, with a sandy bottom, or it may be grown in a pot filled with sand or gravel, and then plunged in water.

(D. Gardener's Dictionary; Babington, Manual of British Botany; Burnett, Outlines of Botany.)

SUC, the species of one of the tribes derived from the Roman 'Successio,' which signifies a coming into the place of another, and Successor is he who comes into such place. The Roman term signifies a coming into the place of another so as to have the same rights and obligations with respect to property which that other had. There might be succession either by coming into the place of a person living, or by becoming the successor of one who was dead. Successio (iii. 77) signifies a coming over or a passing over, an instance of which is the Honorum Cessio according to the Lex Julia. Succession was again either Universal or Singular. The instances of Universal succession (per universum) are the being made a person's heir, giving the possession of the bona of another, buying all a man's property, adopting a person by adoption, and admitting a woman into the union as a wife; in all of which cases the person succeeds to the property of another, and is a passing over at once to the person who was made heir, or got the honorum possession, or bought the whole property, or adopted another by adoption, or married the woman. An instance of singular succession is the taking of the legacy of another by a man's will.

The term Successio is used in our language. We speak of the succession to the crown or the regal dignity, and the term implies that the successor in all things represents the person who
cessor. Indeed, the king as a political person, never dies, and upon the natural death of a king the heir immediately succeeds. The English heir-at-law takes the descendent lands of his ancestor as universal successor; and the successor takes the châteaux royal and others of a similar nature. This takes place at the death of the universal successor. The general assignee or assignees of a bankrupt or insolvent take by universal succession.

Blackstone says that 'corporations aggregate consist of members, each of whom is a part of the corporation and are kept up by a perpetual succession of members, so as to continue for ever.' It is true that when members of a corporate body die, others are appointed to fill up their places, but they do not succeed to the property of the deceased, nor do they simply become members of the corporation. But it has been established in some cases (2 B. & Ad. 840) that the use of the word 'successors' implied that the legislature meant to establish a corporation; and yet it is certain that a foetus of land to a corporation aggregate without the word 'successors' is a valid grant. In a foetus to a corporation sole the word 'successors' is not necessary. The succession in the case of a corporation sole follows the nature of the Roman succession. In the case of a corporation aggregate there is no succession, and the rule that a corporation may be established by the use of the word 'successors' is a statute in no case on the erroneous understanding of the term 'successors.'

SUCCESSION, WAR OF, the name usually given to the war occasioned by the succession of the Duke of Anjou, grandson of Louis XIV. V Honoré of France in Spain, the last male descendant of the Spanish branch of the House of Austria, having no issue nor brothers, the succession to the Spanish monarchy appeared to belong to Maria Theresia, Queen of France, and her brother. The Threser menace to establish a crown of Spain for his son Charles, on account of Leopold's mother being aunt of Charles II. France and Bavaria, on the other hand, maintained that the renunciation alluded to could not prejudice the children, who held their right not by their mother, but by the fundamental law of Spain. Each of these powers endeavoured to influence Charles II. in their favour, and he was at length inclined to name in his will Joseph Ferdinand, Elector of Bavaria, as his successor. The early death of this prince, in 1699, revived the contending claims of the Houses of Bourbon and Austria.

These different claims having excited the apprehensions of a war, the parties interested [Partition Treaty, P. C.] were, on 15th March, 1700, between France, England, and Holland, the details of which will be found in another part of this work. By this treaty, a neutrality was established, by which the territory of Landau on the Rhine, which had long been an object of dispute between the Habsburgs and the House of Baden, became the presumptive heir to the Spanish crown, while the grandson of Louis was allowed the duchy of Lorena, together with the kingdom of the Two Sicilies and the province of Guipuzcoa in Spain. This treaty however was rejected by the emperor, and the consequences of his rejection proved finally fatal to the cause of his son.

On the death of Charles II. (Nov. 1, 1700) a secret will was discovered which named the Duke of Anjou sole heir to the whole of the Spanish monarchy. Though Charles had been influenced in drawing up this will by the intrigues of Madame de Maintenon, carried on through the Marquis d'Harcoeur, the Marquise d'Harcourt, and others, it was expected that a war, with Austria at least, must be the issue of his acceptance of the Spanish crown for his grandson, hesitated before availing himself of the offer, which was rendered the more presumptive by the general feeling of the inhabitants in favour of the House of Bourbon. A council which he summoned on the occasion gave its unanimous opinion in favour of acceptance, and indeed the French king immediately to proclaim the prince of Anjou as his successor, and the news of the death of his heir was the signal of a war which was one of the longest and most general in Europe. On the side of the emperor were the states of Germany, with the exception of Bavaria and Cologne. Most of the powers of Europe however acknowledged Philip V., who made his entry into Madrid on the 14th of April, 1701; and had Louis, at this time, prudently conciliated his measures, he might have secured to his grandson the peaceable possession of the throne of Spain and the universal succession. Peace was moreover of paramount importance to the French monarchy, drain as it was in its resources and weakened in its power by the war which had but lately been terminated by the treaty of Ryswick. [F. C. vol. xxvi. p. 174.]

Age and infirmities had diminished the energies and dampened the military ardour of Louis, while death had deprived him of many of the great men of his minister and general staff, who were the chief instruments in forwarding his reign so illustrious in history; Louvois and Colbert had disappeared from the political stage, together with Turenne, Condé, Créquy, and Luxemburg.

England and the States-General, though they had acknowledged Philip V., entertained fears lest the balance of European power should be disturbed by the union of France with Spain. Louis, on the other hand, far from attempting to dispel these fears, with singular impolicy issued letters patent in favour of Philip, to the effect of preserving his rights to the throne of France. Another measure equally impolitic was the encroachments made at that time by the French in the Spanish Netherlands, on the consequence of their consequent military approximations to the territories of the States-General. This latter measure gave an opportunity to William III. of Orange to engage the Dutch against France; but he found considerable difficulty in bringing the English Court to share his views. An event however soon occurred which removed these difficulties; it was the death of the exiled king of England, James II., and the recognition by Louis of his son as king of Great Britain. This was the pretext which the treaty drawn up at the Hague on September 7, 1701, and generally known under the name of the Second Grand Alliance, was signed by the plenipotentiaries of the Emperor of Germany, the States-General, and the King of England. The principal objects of that treaty are detailed in another part of this work. [Hague, Alliance of the P. C. S., in which by an over-night treaty of Charles III. is put for that of Philip V.] This alliance was subsequently prolonged by the Kings of Portugal and Prussia and the Duke of Savoy.

On the death of the King of England, his successor, Queen Anne, followed his policy in adhering to the alliance of the Hague [Annex, P. C.], and three months had not elapsed after her accession before war was declared by the powers united by that treaty against France (4th May, 1702). The commencement of the war for some time maintained the former glory of their arms, and defeated the Imperialists on the Upper Rhine, but the Earl of Marlborough [MARBOROUGH, THE EARL OF] had, however, succeeded in the Anglo-Dutch army, made considerable progress in Flanders, while the combined fleets of England and Holland destroyed a French fleet in the Bay of Vigo, The fortress of Ferrol was taken, and the Prince of Condé was defeated at Lévis of Baden. In Italy, Prince Eugene, who had the command of the German army, was unable, through the deficiency of his resources, to attempt any measure of importance.

_Eugene, P. C._

The following year was spent by Marlborough in reducing the fortified places on the frontiers of the Spanish Netherlands. In Southern Germany the contest was more unfavourable to the allies. The French Marshal Villars [VILAR, P. C.] had succeeded in crossing the Rhine and in uniting his forces with those of the Elector of Bavaria. In Italy and Alano the French had likewise the advantage in arms. Their cause however was considered in danger by the defection of the Duke of Savoy, who joined the allies, as did also the king of Portugal. The campaign of 1704 was more unfavourable to the French armies. Marlborough, having secured the safety of the Netherlands determined upon marching into Germany to the aid of the emperor, whose capital was menaced on one side by the French and Bavarian armies, and on the other by the Hungarians, who had taken the occasion of the war to attack a revolt, that was also resolved upon by the allies to unite the forces under the three Generals—Marlborough, Eugene, and Lewis of Liden, while General Stabenberg was to remain in Italy. The junction of their armies was arrived at at Heilbronn; but it was agreed among them that Prince Eugene should direct his march along the Rhine, while the two other generals directed their courses to the Danube. The passage of the Danube was

_Vol. 11._ 4 _F_
bravely but unsuccessfully disputed by the Bavarians near Donauworth. Advantage was taken of their success by the allies to offer peace on favourable terms to the elector, if he would withdraw from the alliance with France. The advances of Marshal Taland with a French army of 30,000 men deterred the elector upon refusing these proposals; at the same time Eugenio had joined Marlborough with 20,000 men; the Prince Eugene was now the obstinate, in which Eustace should demand that their plans, was sent to reduce Ingolstadt. On the 13th August a decisive engagement took place, which terminated in the complete defeat of the French and Bavarians. The details of this important battle will be found in the articles BLESHEIM and MARLBOROUGH, P. C.

This disaster was followed by the loss of Bavaria, which was occupied by the Imperials, and the elector was compelled to cross the Rhine with his French, and to take up his position at Brussels. In Italy and Spain the French obtained some advantages, which however were counterbalanced by the loss of the important fortress of Gibraltar, which fell into the hands of the English on the 24th July, 1704. [GIBRALTAR, P. C.]

The next year, 1705, the Emperor Leopold died, and was succeeded by his eldest son Joseph, whose character for energy and determination formed a favourable contrast with that of his father. After some hesitation, he decided upon vigorously pursuing the war in support of the claims of his brother Charles, who the year previous had proceeded to Spain with an army of 40,000 men and 1200 horse. The French, who had been besieging Gibraltar, and were now 4000 in number, under General Lillo; Marshals Villars, with the French army of nearly equal strength, covered Dossay and Arras. Eugene and Marlborough, instead of attacking him, marched against the important fortress of Tourcoing, at the head of 40,000 men. These operations were directed against Mons, which place Villars was desirous of protecting, and he accordingly encamped within a league of it in a strong position and in bivouac. No siege was lost by the allies in attacking him in his intrenchments; and, after the contest the most obstinate and sanguinary during the war, victory remained once more on the side of the allies (11 September). [MAESTRICHT, P. C.] The surrender of Mons was the immediate result of this victory. Another campaign had terminated unfavourably to Louis; he again applied for peace, but the same disadvantageous terms were proposed to him, and the cruel alternative was again presented to him of continuing a disastrous war or of waging one against his child; as before, he chose the former.

The campaign of 1710 was marked by the reduction of Dossay and other strong places on the Netherlands frontier, and in Spain by the successes of Charles at Almenara and Saragos, which enabled him to enter Madrid. Reverses, however, soon attended his arms; fresh troops arriving from France, the allies took the offensive, and they were rejected chiefly through the influence of the pensionary Antony Heinsius.

In 1707 a considerable portion of the Spanish inheritance was gained by the allies, who, in the person of the Empress, had already been secured to them by the battles of Turin and Ramillies. Louis at this time determined upon a diversion in his plan of attack, which was soon followed by important consequences. The large body of troops which had been forced to evacuate Italy he collected together, and, placing them under the command of the Duke of Berwick [BERWICK, JAMES FIFTH DUKES OF, P. C.;], sent them into Spain, which he resolved to invade in an attack upon Barcelona; and the English and Portuguese entered Madrid, which city however they were unable to retain. At this juncture of affairs a suspension of hostilities was concluded between the allies, but they were rejected chiefly through the influence of the pensionary Antony Heinsius.

of Marlborough of his influence, measures of peace were strongly advocated. [Anne, P. C.] Secret negotiations were set on foot between the Courts of England and France, which ended in a preliminary treaty of peace being signed in London on October 8, 1711. The conferences for a general peace, which took place at Utrecht was selected as the place where they were to be held.

The conference which took place at Utrecht in the early part of the year 1712 met with several interruptions, arising from the previous differences of opinion as to the right of the powers who composed the grand alliance. The victory obtained by Marshal Villars over the Earl of Albermarle at Denain (24 July, 1711) [Villars, P. C.], and the consequent recovery of Dunkirk, induced the Dutch to make peace with the French, and rendered the allies more tractable. Peace was at length signed at Utrecht in the month of April, 1713, between France and England, the United Provinces, Prussia, Portugal, and Savoy: the Emperor alone refused to take part in it. A full detail of the terms of that treaty will be found in another part of this work [P. C. vol. xiv. p. 174]. The real gain by it was undoubtedly the French King, who obtained no more than the advantages which it had been the object of the war to prevent his acquiring; it was also productive of considerable odium against the English ministry. [Harley, P. C.]

The terms of the treaty, now deserted by his allies, was compelled to negotiate alone a peace, which became important even for the security of his hereditary states. It was brought about by the moderation of the two great generals Eugene and Villars and Joubert's staff. The terms of peace, in which they had fought, proved themselves the most desirous of promoting peace. They communicated negotiations at the Castle of Hastings in November, 1712, and a treaty was there concluded on the 7th March, 1713 [Kastorf, P. C.]; and the terms of it were definitely agreed upon on the 7th September following at Baden in Austria. [Baden, TREATY OF P. C. vol. xiv. p. 174.]

The King of Spain acceded to these treaties, and to the deserts of peace, and signed the treaty at Aix-la-Chapelle.

SUCKET, LOUIS GABRIEL, Duke of Albufera and Marshal of France, was a native of Lyon, where his father was a manufacturer. The year of his birth is stated by some authorities to have been 1770, by others 1772. On the break-up of the French Revolution, he was appointed to the position of a volunteer in the cavalry of the national guard of Lyon; shortly afterwards, he became captain of a volunteer company raised in the department of Artois, which he commanded during four months, when he was appointed to the command of a 'bataillon' in the troops of the above-named department. In his capacity, it is stated, he was compelled to be the active witness of many atrocities, committed in the name of the law by the deputies of the convention, Majeur. He was present at the siege of Toulon in 1793; from thence he was transferred to the army of Italy, and was attached to the brigade under the command of General Lafayette. In this campaign he was distinguished himself at the combat of Longjumeau (23rd November, 1795), where he captured three Austrian standards. He afterwards served with distinction in the same campaign under the command of the General Augereau [Augereau, P. C.], and Massena [Massena, P. C. S.], and received several wounds. He was selected by Massena to present to Bonaparte the standards which had been captured during the year 1795, in which he was born. It was on the field of battle of Neumark (2nd April, 1797) that he was raised to the rank of 'chef de brigade.' He afterwards joined the army in Switzerland, where he was instrumental to the conclusion of the Treaty of Aarau, at Berne and Bressbourg. This treaty did not prevent the war being rekindled in Switzerland, and in it Suchet displayed considerable skill; it was there that he first gave proof of his abilities as a tactician, which afterwards raised him so high in the estimation of Bonaparte. The important part which he acted in this campaign was recognised by his chief, who deputed him to Paris to present the Directory twenty-three standards taken from the enemy.

When the expedition to Egypt was determined upon, it was originally intended that Suchet should be included among the military commanders selected to act under Bonaparte; the disordered state of affairs, and disbandment of the army of Italy, and the representations of General Brune, who commanded it, caused him to be retained there with the rank of Major-General of Brigade. In his new and important position he made many strenuous endeavours to renew the ancient discipline and to anestimulate the condition of the soldiers; these endeavours were construed by the suspicious government at Paris into an attempt to introduce in the army a new and aristocratic rule. His record was declared unsuited to the strong remonstrances made on the subject by General Joubert, who was amongst the most popular and successful of the republican generals of that period. On his arrival at Paris, he succeeded in clearing himself of the charges which had been brought against him, and he was transferred to a command in the army of the Danube. He there rendered himself conspicuous by the able manner in which he reconciled the skilful manoeuvres of General Masséna in the Grisons. [Masséna, P. C. S.] The successes which attended the French armies in Switzerland were counterbalanced by the disasters of General Schérer in Italy; these disasters necessitated the immediately appointment of a vigorous commander, and Joubert was again intrusted with the chief command. On this occasion Suchet was recalled from the army of the Danube, and placed at the head of the troops, and to his military reputation; the careful avoidance of error in his movements and manœuvreurs, the skilful disposition of his troops, whether acting independently or in conjunction with the main army, as they procured him important successes. Soon he attracted the notice of Bonaparte when he joined the Italian army, and he was appointed by him second in command to Masséna. In this capacity he particularly distinguished himself in the actions of Sarrener, Mondovi, and the bridge of Ceicio (7th and 8th May, 1800). With a body of eight thousand men, advantageously posted, he checked the advance of General Mélas, who had five times his numbers, and for a long time harassed his army, whose retreat he had cut off; he thus afforded a powerful co-operation to the main army of the French, which, under the command of Bonaparte, was at that time crossing the Great St. Bernard. [Bonaparte, P. C.] General Suchet, after these operations, rejoined Masséna on the plains of Alesandria, and was present at the battle of Marengo. When, in consequence of this decisive battle, the city of Genoa again fell into the hands of the French [Masséna, P. C. S.], the Emperor Napoleon sent to Suchet a letter giving him the command of the main army of the French, which, under the command of Bonaparte, was at that time crossing the Great St. Bernard. [Bonaparte, P. C.]
ally contributed to the success obtained by Savary, Duke of Rovigo, over the Russian General Essen, who, with twenty-five thousand men, attacked the French on the banks of the river Narrew (16th February, 1807), and was repulsed with great loss to his side, and with great loss. The reputation which Suchet had acquired in these engagements, as a brave soldier and a skilful tactician, induced Napoleon to entrust him with a separate command. An opportu-

nity was afforded to test the value of the French army in the Peninsular War, by a successful invasion of Spain in 1808, and he gave him the command of the fifth division of the army, having previously raised him to the high grade of the Legion of Honour. Suchet's services in Spain were acknowledged by the commission of 20,000 francs, and the title of Count of the Empire. After assisting for a short time at the siege of Saragossa (SARAGOSA, P. C.; LAMBE, P. C.S.), he was appointed to the important command of Governor and chief of the French army in the province of Aragon. This brought us to the most illustrious period of this general's military life; the campaigns which followed under his command, are among the most brilliant recorded in history, and it is to be regretted that sufficient justice has not been rendered to his merit by the English annalists of this war, previous to the time of General Napier. To this distinguished and impartial historian has been reserved the honourable task of raising the character of an enemy to the position he deserves in public estimation. When General Suchet was placed at the head of the forces in Aragon, he found the army so demoralised and dispirited as to be reduced to disorder and demoralisation. In applying the measures to restore this discipline, he evinced considerable discernment, prudence, and energy; no longer thwarted in his efforts by the factional opposition of mere theatrical statements, and uncontrolled by the influence of the Direction, he was able to specify effects and accomplish much greater ends. This important purpose, "Suchet," says the historian above referred to, "was no ordinary man; and with equal vigour and prudence he commenced a system of discipline in his corps, and of order in his government; that afterwards carried on by himself, with scarcely a check, from one success to another, until he held the rank of marshal for himself, and the honour for his corps of being the only one in Spain that never suffered any signal reverse." (Napier, History of the Peninsula, War, vol. ii, p. 97.) In 1810 General Suchet received orders from Madrid to lay siege to the strong fortress of Lerida, the approaches to which were covered by the Spanish General O'Donnell and a strong body of Catalan troops. The defeat of this general was followed, after a gallant and obstinate resistance, by the surrender of the fortress which he had protected (14th May, 1810), in which were found five hundred pieces of artillery. The fall of Lerida was followed by that of Mequinez (8th June, 1810), and Tortosa (2nd January, 1811). These successes were followed by one still more important, the taking of the city of Tarragona (TARRAGONA, P. C.), which was defended by a garrison of eighteen thousand men; the city fell into the hands of the French after a siege of two months, or rather, as Suchet himself expressed it, after a succession of three sieges and five assaults. This victory was also marked by a French achievement of five thousand cannon and abundant munitions. (TARRAGONA, P. C.) The auspicious nature of this siege may be judged from the fact that upwards of nine thousand Spaniards of the garrison are said to have perished. The occupation of Mont-Serrat, a place of such great strength that it was deemed impregnable, followed soon after the capture of Tarragona. These brilliant services were justly appreciated by Napoleon, who rewarded them by raising Suchet to the dignity of a Marshal of the Empire. In the latter end of the year 1811 Suchet directed the operations of his army against Murviedro, the ancient Saguntum (HANIBAL, P. C.), the fortifications of which had been constructed by a considerable expense; the defeat of General Blake and thirty thousand men under its walls, was followed, after about a month's siege, by the fall of this important fortress. A reinforcement of fresh troops having arrived from Navarre, Suchet next proceeded to invest the city of Valencia, which surrendered to him by capitulation on 10th January, 1812. The fall of this city, and of some fortresses in its neighbourhood, was followed by the occupation of the city of Huesca, one of which it was declared that had been the scene of his last successes, became the title of the dukedom to which he was raised by Napoleon, with all to this title an extensive and valuable domain. But he obtained the title of the dukedom by the posteriority of the general expression of the Spaniards under his rule, that he mitigated the horrors of war by his humanity, and dealt equal justice to the conquerors and to the conquered. "The mission imposed upon him had been to conquer and to subdue: he was required to provide for the expenses of the war by the success of war; the mission, however, which he imposed upon himself was to augment the power of Spain, to increase its dignity, and to diminish the taxes of people artisans, and cultivators, and to compose of enlightened and respectable men. He called together an assembly of persons of every class of society, and representative of every province, and reduced the war and equity to divide its burdens; and in them he render a faithful and detailed account of the manner in which these taxes were employed. He manifested the same spirit of confidence and justice towards the soldiers under his command, and found it productive of the most beneficial results." The success which attended the British arms under Lord Wellington, and the decisive victory which he obtained at Vittoria, compiled a large portion of the French army to retreat beyond the Pyrenees, and, in consequence, Suchet found himself under the necessity of abandoning the eastern provinces of Spain, and to fall back upon Catalonia, where he maintained himself for some time. Obliged at length to evacuate this province, and to retreat towards the frontiers of France, he effected this retreat in the attitude of a conqueror, and secured the submission of the provinces in his path. The occupation of Narbonne, he signified, on 14th April, 1814, his adhesion to the decrees of the senate directed against Napoleon. Employed to receive Ferdinand VII. (Ferdinand IV.) of Spain and Casimir P. C. at Bordeaux, he was present at the abdication of the King of Spain and the assassination of the Duke of Berri. He accompanied the King of Spain to the French army, and to present him to the Spanish army, he was publicly thanked by the king for the manner in which he had carried on the war against his subjects. The gratitude of the Spanish nation for the administration of the war was further evinced by the general testimony which was borne to his justice and humanity, when, in 1823, the French saint occupied the scene of his exploit. The correct view taken by Suchet, with regard to the life of Ferdinand, will be seen by reference to Montblonhol, History of the Captivity of Napoleon, vol. ii, p. 350. The speedy adhesion of Suchet to the Bourbons was rewarded by his being created a member of the new peerage, and his appointment to the command of the tenth military division, of which the head-quarters was Strasbourg. On the return of Napoleon from Elba, though he retained his fidelity to the Bourbons, in 1815, he was hurried back to France, he renewed his allegiance to his former chief, and accepted the command of the army of the Alps, with which he obtained several important successes over the Piedmontese, and reduced to submission the state of forty thousand men, and on the approach of the main body of the Austrians, nearly one hundred thousand strong, he was com- pelled to fall back upon Lyon, for which city, by his judicious management he was made a member of the council of the city and condottier of Lyon. Suchet, in the face of the conditions in it being that all the valuable munitions of war contained in that city should be respected by the enemy. On the second restoration of the Bourbons, he remained for some time in disgrace, and was deprived of his civil though not of his military honours. He was however re- stored to his position in the peerage by a royal ordinance, dated the 6th of March, 1818. That he entirely recovered the favour of the king may be presumed from the fact that he was chosen to assist at the birth of the present Duke of Bordeaux. On the French expedition to Spain, in 1823, it was generally expected that Marshal Suchet would have been selected to accompany the Duke of Angoulême, as his principal advisor, but he was already suffering severely from the disease to which he shortly afterwards fell a victim. He died at Marseille on the 7th of January, 1826, leaving behind him a young widow and several children. During the latter years of his life he was occupied in composing a memoir of his campaigns in Spain, which has since been published. (McC.theros, Hist. of the City of Berlin, p. 574.)
The reputation of Suchet stands deservedly high amongst the generals of Napoleon. His military career was uninterrupted by any of the excesses which have disgraced so many of his contemporaries. Brought up in the school of Masséna, he rivalled his military skill without imitating his vices. It is true that his entrance by storm into Tarragona was marked by the rapine and inhumanity of his soldiers; but he spared the lives of the defenders of our own army at Badajos and St. Sebastian, and it would be unjust to throw the odium of them on his illustrious commander. The inability of a chief perfectly to restrain the frenzied violence of his soldiers on such terrible occasions is a melancholy fact which the history of all ages has established. We have already dwelt upon his qualifications as a military and a civil ruler. The high opinion entertained of Suchet by Napoleon has been recorded by Valfré, Le Bas, and Las Cases. On the question being asked him by the former, who, in his opinion, was the first of his generals? he replied, 'I think that Suchet is probably the first. Massena was; but you may say that he is dead' (1817), alluding to the complaint under which that marshal was fast sinking. On another occasion, at St. Helena, Napoleon remarked, 'that if he had had two such field-marshals as Suchet in Spain, he should not only have conquered, but kept the Peninsula. His sound judgment, his governing yet conciliating spirit, his military tact, and his bravery had procured him astonishing success.' (Cour and Camp of Bonaparte, p. 410.)

SUCHOSAURUS, the name given by Owen to a fossil Saurian, of which the remains were discovered in the strata of Sault-Hellas, in Southern France. The remains consist of a number of plates, containing the remains of the bones of a Sauropsidian, but such as do not belong to the Sauria. The name is derived from Suchan, a town near Sault-Hellas, whence the remains were discovered, and saurios, a dragon, in Greek.

SULPHURATION, or SULPHURING, is the process of bleaching employed to give whiteness to silk and woollens by exposing them to the fumes of burning sulphur. For this process a detached chamber, without a chimney, is made use of, but so constructed that, when required, a current of air may be passed through it. According to Berthollet, 100 pounds of silk, stuck on perches, are placed at a height of nearly seven feet, and about two pounds of sulphur, reduced to coarse powder, are put into an iron pot, containing a small quantity of ashes; the sulphur is fired in several places, and the chamber well closed to prevent the loss of sulphurous fumes; afterwards the windows are opened to let them escape and to dry the silk. In winter, after the smell of the sulphurous vapour has ceased, the windows are shut, and charcoal is burnt in the chamber, in order that the sulphurous fumes may be absolved. The silk becomes perfectly white, and is rendered fit for subsequent operations. Woollen cloths are treated nearly in the same manner.

SWITZER COLLEGE OF. [Surgons, College or, P. C. S.]

TENEMENTS, of Surgons, College or, London, COLLEGE OF. [Surgons, College or, P. C. S.]

The new charter was granted to the College of Surgeons in the 7th year of Victoria, by which it is declared that the name of the college shall henceforth be the Royal College of Surgeons of England; and that a portion of the members of the said college shall be fellows thereof, by the name of The Fellows of the Royal College of Surgeons of England. The charter declares that the present president and two vice-presidents and all other the present members of the said council of the said college and such other persons, not being less than 250 nor more than 300, and being members of the said college, as the council of the college, at any time before the expiration of three calendar months from the date of the said charter, shall by vote, be fellows in manner by the charter directed; together with any such other persons as the council of the said college, after the expiration of the said three calendar months and within one year from the date of the charter, shall appoint in manner by the charter authorized, shall be fellows of the said college. But no person, except as hereinbefore named, is to be a fellow before the age of twenty-five years, and compiled with such rules as the council of the college shall think fit and by a by-law or by-laws direct; nor unless he shall have passed a special examination by the council of the college. But no member shall be admitted as a fellow, as last mentioned, is to become a member of the College by such admission, if he is not already a member. Henceforth no member of the College who is not a fellow is to be eligible to a member of the College. And any person who shall have been elected by the council, either from the members of the council or from the other fellows of the college, or from both of them; and all future examiners of the College shall hold their office during the pleasure of the council. The charter contains other regulations, and confirms the powers of the college and the council, except so far as they are altered by the charter; and it declares that no by-law or ordinance hereafter to be made by the council shall be of any force until theウンshan shall have signified its approval thereof to the College under the hand of one of the principal secretaries of state, or otherwise as in the charter stated (22). The by-laws and ordinances of the Royal College of Surgeons are declared to remain in force, and the regulations as to the candidates for the fellowship (sect. 1), for the examination of candidates for the fellowship (2), admission of fellows (3), election of members of council (6). By section 1 it is required that every candidate for the fellowship, among other certificates, shall produce a certificate, satisfactory to the court of examiners, that he has attained a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics. The subjects of examination for the fellowship are Anatomy and Physiology on the first day, and Pathology and Therapeutics and Surgery on the second day. The examination is to be by written answers and oral examination. The examination of each candidate may be interrogated by the examiners, on any matter connected with the questions or answers. In the anatomical examination the candidate must also perform dissections and operations on the dead body in the presence of the examiners.

The members of the College are admitted by diploma after examination before the court of examiners, and their diplomas confer upon them the right of practising surgery in any part of the British dominions.

The council of the College have at various times required certain qualifications of age, education, &c. from candidates for examination. The regulations last issued are dated October, 1841.

The examinations of members are conducted twice a year, or, if the candidate desire it, in writing. The examinations are almost exclusively anatomical and surgical, and the examination of each candidate occupies about an hour and a half, during which time he is usually questioned by four of the examiners in succession. According to the financial statement (June, 1843), the receipts of the College for the previous year were as follows:

<table>

The receipts of the College for the previous year were as follows:
for the case in which the reflecting surface is a plane, that it is not necessary to prove that the equal angle of incidence and reflection is that of the ray of light parallel to the normal, having been given only that of the ray parallel to the tangent plane, and that this is that angle which the line joining the point of reflection to the intersection of the tangent plane with the axis of incidence makes with the plane of incidence.

For the case in which the reflecting surface is a plane, that it is not necessary to prove that the equal angle of incidence and reflection is that of the ray of light parallel to the normal, having been given only that of the ray parallel to the tangent plane, and that this is that angle which the line joining the point of reflection to the intersection of the tangent plane with the axis of incidence makes with the plane of incidence.

For the case in which the reflecting surface is a plane, that it is not necessary to prove that the equal angle of incidence and reflection is that of the ray of light parallel to the normal, having been given only that of the ray parallel to the tangent plane, and that this is that angle which the line joining the point of reflection to the intersection of the tangent plane with the axis of incidence makes with the plane of incidence.

For the case in which the reflecting surface is a plane, that it is not necessary to prove that the equal angle of incidence and reflection is that of the ray of light parallel to the normal, having been given only that of the ray parallel to the tangent plane, and that this is that angle which the line joining the point of reflection to the intersection of the tangent plane with the axis of incidence makes with the plane of incidence.

For the case in which the reflecting surface is a plane, that it is not necessary to prove that the equal angle of incidence and reflection is that of the ray of light parallel to the normal, having been given only that of the ray parallel to the tangent plane, and that this is that angle which the line joining the point of reflection to the intersection of the tangent plane with the axis of incidence makes with the plane of incidence.

For the case in which the reflecting surface is a plane, that it is not necessary to prove that the equal angle of incidence and reflection is that of the ray of light parallel to the normal, having been given only that of the ray parallel to the tangent plane, and that this is that angle which the line joining the point of reflection to the intersection of the tangent plane with the axis of incidence makes with the plane of incidence.

For the case in which the reflecting surface is a plane, that it is not necessary to prove that the equal angle of incidence and reflection is that of the ray of light parallel to the normal, having been given only that of the ray parallel to the tangent plane, and that this is that angle which the line joining the point of reflection to the intersection of the tangent plane with the axis of incidence makes with the plane of incidence.
Next, imagining Q to be very near N, let fall QP perpendicularly on NN', and QP perpendicularly on QQ'; then

\[ NT = NN' - QQ', \text{ and } NT = NN' - QQ'; \]

or, substituting the values of NN' and QQ',

\[ RQ = \frac{NN'}{NN'} - QQ'; \]

therefore

\[ NQ : NT = 1 : R. \]

Now NQ being considered as a straight line, it is a common hypotenuse to the right-angled triangles NQP and NQ; hence

\[ NQ : NT = \sin NQ : \sin NQ. \]

But ZQ and NQ' being perpendicularly to the refracting surfaces, NQ' is the complement of ZQP, and is therefore equal to the complement of QQ' or the angle of refraction of the second velocity through S and touching the surfaces of the several waves would fall between SN' and SS' : such surface would then be the front of the refracted wave; and thus the front would, in a given time, pass through a least interval from the reflecting surface (or from the radiating point) than it actually passes through in consequence of the partial waves taking the directions NN' and QQ'. In like manner with respect to refraction: if the wave velocity be less than that of the front of the wave, it is evident that the curve surface passing through S and touching the surfaces of the several waves will fall between SS' and SN'; such surface would be the front of the refracted wave; and the conclusion corresponds to that which has been stated for a refracted wave. Therefore in both cases the time, reckoning from the moment of setting out from the radiating point, or from the reflecting or refracting surface, during which the general wave arrives in any given position, as \( SS' \), will be the least possible.

SWITHIN, ST. Albans. Edward Bishop of Winchester, was born in the early part of the ninth century, but the exact year is not ascertained. He was ordained priest in 880 by Dunstan, Bishop of Winchester, and was soon after appointed by King Egbert to the see of Winchester. He is said to have been the son Ethelwine. In the reign of the latter he became chancellor, and was intrusted with the education of Alfred, whom he accompanied to the Holy Land. The see of Ethelwine was assigned to Swithun to Ethelwine in 918. His bishopric was the ecclesiastical affairs of his kingdom were rewarded by his elevation in 952 to the see of Winchester, vacant by the death of Helgenst. He is supposed to have been the originator of the payment of Peter's Pence to Rome, though there is much reason to believe that this tribute had an earlier origin. Peter's Pence, P. C., and also to have procured the first act of the Witenagemot for enforcing the uniform payment of tithes.

William of Malmesbury says of St. Swithin that he was a rich treasure of all virtues, and that those in whom he took most delight were humility and charity to the poor. He adds that he acquired the name and devoted himself exclusively to the spiritual administration of his diocese; in his frequent visitations of it, he travelled with his clergy on foot, and for the most part by night, in order to avoid the suspicion of restitution. He died on the 2nd July, 862. His last request was that he should be buried in the churchyard of Winchester, 'ubi cadaver et pedibus praeteractum et stillificdas e coelo coronas ineditas esse omnia.' His name being admitted into the calendar as that of a canonized saint, it was resolved to transfer his remains to the cathedral, and to place them in a magnificent shrine prepared for the purpose by his great friend Aldhelm, abbot of Malmesbury. This latter, who died on the 15th of July, was decayed for forty days in consequence of the severe rainy weather which occurred, and hence arose the well-known tradition of which the prevailing notions are thus expressed in a Scotch proverb:

'Saint Swithin's day, gie ye do mae, For forty days it will remain; Saint Swithin's day, an ye laic, For forty days tae rain nae mae.'

In France the day of the festival of St. Gervais (19th June) is marked by a similar superstition:

'Saint Gervais jour, an ye laic, For forty days tae rain nae mae.'

These superstitions are not however altogether unfounded, as experience having shown that whenever a wet season sets in about the end of June to the middle of July, it generally lasts for forty days, which corresponds to the majority of our summers, a rainy season of about forty days, often set in nearly at the time indicated by the tradition of Saint Swithin. (See an interesting paper on the subject in the Penny Magazine for 1832, p. 140.)

The festival of St. Swithin in the Roman Martyrology is the 2nd of July, the day of his death, but in England it was celebrated on the 15th of July, the day appointed for the translation of his relics to the Cathedral of Winchester.

[Winchester, P. C.]

SYCOCHRUS, a genus of fossil Cricoida from the mountain limestone of Yorkshire. (Austin.)

SYDENHAM, CHARLES EDWARD POULETT THOMSON, LORD, was the son of John Poullet Thomson, Esq., of Waterley Abbey and Roehampton in Surrey, the head of the mercantile firm of J. Thomson, T. Bonar, and Co., which had been long one of the most eminent houses engaged in the Russian trade. Mr. John Thomson, who assumed the name of Poullet by sign-manual, in 1820, in memory of his mother, married, in 1781, Charlotte, daughter of Dr. John Bonar of Culross, and by her he had a family of nine children, of whom the subject of the present notice, born at Waterley on the 13th of September, 1799, was the youngest. There were two elder sons, Andrew and George, of whom the latter, now George Poullet Scroppe, Esq., is the present member for Stroud, and the author of 'Principles of Political Economy,' 12mo., 1839, and of 'The Life of Lord Sydenham,' 8vo., 1848.

Charles is stated by his brother to have been remarkable in his infancy for his grace and beauty; but the story which he tells of the child, who had attracted the notice of George III. at Weymouth, in the summer of 1805, having been placed by his majesty in the army of the guards, 'he cannot be correct in all respects;' for Mr. Pitt was not then prime minister, as is assumed, and could not have been in attendance upon the king in that capacity. It seems unlikely indeed that he should have been with the king all in that year. Lord Sydenham was never at any public school or university; and he left his native country at the age of sixteen, to be placed in his father's house of business at St. Petersburgh, and then under his direction in his absent brother. He returned to England in ill-health in 1817; then made a tour to the south of France, Switzerland, and Italy; after which he took his place in his father's counting-house in London, in the summer of 1819. In the spring of 1821 he was again sent out to St. Petersburgh, this time as a partner in the firm; and here he remained for two years. The greater part of the winter and spring of 1824-5 he spent in Vienna; whence returning by Paris to England, he assumed, in conjunction with his brother Andrew, the chief conduct of the business in London.

Sanguine, ambitious, and self-confident, he involved himself to some extent in the American mining speculations of 1825. Meanwhile he had become intimate with the late Mr. Bentham and Mr. James Mill, with Mr. Warburton, Mr. Home, Dr. Bowdler, and Mr. Croker, and had set his heart upon entering public life. He obtained a seat in parliament for Dover, after an expensive contest, at the general election in the summer of 1826. His rise from this date was very rapid. Voting steadily with the extreme section of the Opposition, he spoke but seldom, and almost exclusively upon commercial questions. On the first occasion however on which he delivered himself at any length, in a speech which he made on the subject of the Reform Act in May, 1827, he made a very favourable impression on the House, and had the gratification of being warmly complimented.
by Mr. Hukisson. After this, whenever he rose he was listened to with attention. He was again returned for Dover in 1830; and when the Whigs came into power, in November of that year, he was appointed to the Hereditary Seat of Vice-Admiral of the Board of Trade and Treasurer of the Navy. He was returned again for Dover after his acceptance of office, and also to the succeeding parliament, which met in June, 1831. At the general election in December, he was returned both for Dover and for Manchester; he elected to sit for the latter place; and continued to represent Manchester as long as he remained in the House of Commons. Meanwhile on the recommendation of the Minister in June 1832, arising out of the secession of Lord Stanley and Sir James Graham, Mr. Poulett Thomson was made President of the Board of Trade, in the room of Lord Auckland, who was removed to the Admiralty; and on the recovery of power by his party in April, 1835, after Sir Robert Peel's short administration, he resumed that office with a seat in the cabinet. So early as in the beginning of the year 1836, if there be no misapplication of the date in Mr. P. Scrope's narrative, it had been in contemplation to remove him to the House of Lords, in order to relieve him from the fatigue of the long-sitting in the Commons, under which his health was already beginning to break down; but circumstances, it is added, for a time put a stop to this plan. At last, towards the close of the session of 1839, on the elevation of Mr. Scrope, being by his choice between the chancellorship of the exchequer and the government of Canada; and accepted the latter. He was sworn into his new office before the Privy Council on the 29th of August; he arrived in the 19th of September, and landed in Quebec on the 19th of October. Of his administration in Canada, which was highly successful, Mr. Scrope has published a very full narrative, which was drawn up by Mr. Murdoch, the civil secretary. In August, 1840, the government-general was raised to the peerage by the title of Baron Sydenham, of Sydenham, in Kent, and Toronto, in Canada. But on the 4th of September, 1841, while in a weak state of health, he had misfortune to learn that his horse, which stumbled and fell upon him, and to sustain a fracture of the principal bone of his right leg, besides other serious injuries; and his death followed on Sunday the 15th of the same month. The most remarkable quality that Lord Sydenham possessed was great decision of character, arising from clear-headedness and self-reliance. His activity, zeal, and extensive information also made him an excellent man of business, and his very attractive manners added to his value as a partizan. (Memoir, by G. Poulett Scrope, Esq., M.P.)

SYENE. (Egypt, P. C.)

SYLVESTER, JOSUA, was born in 1683. He appears to have engaged in mercantile pursuits; and was a merchant of the company of merchant-adventurers at Stade, for whose secretaryship he was a candidate in 1697, recommended by the English Company of Merchants in Stade. His father, however, had always remained a poor man, and to have been of a roving disposition. At the latter end of his life he emigrated to Holland, and died at Middelburg in 1618. Both in his opinions and in his choice of friends he was destitute; and the numerous works, chiefly translations from the French, which he ever possessed, his literary reputation, show a warmly devotional and serious tone of feeling. He was not however remiss in courting the patronage of the great. To King James VI. he addressed many salutary dedications; and it was probably in compliment to him that he selected the topic of one of his original poems, which is thus entitled: 'To Tobacco botted, and the Pipes shattered (about their Ears that idly isolate so base and barbarous a Weed, or at leastwise over-love so lusomthe a Vanity), by a Valley of holy Shot thundered from Mount Helicon.' He is chiefly known now on account of the obligations said to have been incurred by Milton to his principal translation, that of the 'Divine Weeks and Works' of Du Bartas. [BARTAS, D., P. C.] There are two collected editions of Sylvester's works, both in folio, and commencing with 1672 and 1674. The dates are 1663 and 1681. The second of them contains a supplement of posthumous poems; among which is that tasteless alteration of the 'Round Ears,' which caused this fine poem to be erroneously attributed to Sydney.

SYMPHOEUSIS (from sympoiesis, compression, and pseu, measure), is an instrument which was invented by Arti, of Edinburgh, in 1619, to serve as a barometer, for the purpose of measuring the degree of the atmosphere, or exhibiting the variations of its density near the earth. An account of its construction is contained in the first volume of the 'Edinburgh Journal of Science.' It consists of a glass tube B about eighteen inches long and seven-eighths of an inch in diameter, externally and internally: at the upper extremity is a cylindrical vessel A half an inch in diameter internally and two or three inches long; and there is a hole in the bottom of it in which the vessel is fixed, and in the former vessel C, of about a half an inch in diameter internally, terminates also in a vessel C of an oval form horizontally. The vessel A and the upper part of the tube B are filled with an elastic fluid, so that, when the vessel being inverted, the vessel C and the lower part of the tube contain a-)lmond-oil tinctured with some colouring matter, as suchas root. In order to introduce the gas and oil, the extremities a and b of the vessels A and C being open, and the former extreme being drawn in the form of a slender tube, the instrument is quite filled with mercury; then, being held in a horizontal position with the orifice b covered by the finger, that the mercury may not come out, the slender pipe at a is put in communication with the gasometer. The hydrogen gas entering at a, and the instrument being now held in the horizontal position, on removing the finger from b the mercury will flow out till its upper surface is at the same level in the tube B and the vessel C, the gas occupying its place in the former. The extremity a then being communicated with the atmosphere, and vessel C being inverted, the mercury in C runs out, while that which remains in the tube B prevents the gas from escaping. The instrument being afterwards returned to its former position, the vessel A uppermost, the oil is poured into the vessel C: then, the gas being heated, by its expansion it drives the mercury in B into the vessel C; and, the instrument being now held in an inclined position, the oil is by the pressure of the atmosphere forced into the tube, in proportion to the gas by cooling becomes contracted in volume. The remaining mercury is lastively poured out of the vessel C; and the end b being left open, the pressure of the atmosphere on the oil is, the instrument being again put in a vertical position, a counterbalance to the weight of the column of oil in B and to the expansive force of the compressed gas which is in the upper part of the tube and in the vessel A.

In order to form a scale for the symphoeusis, the instrument, together with a good barometer and a thermometer, must be placed in a glass receiver in which, by proper syringing, the air may be rarified or condensed at pleasure: then, on bringing the air in the tube successively to such states with respect to density, that the top of the column of mercury in the barometer may stand at 27, 28, 29 and 30 inches, and marking the points on the tube or frame of the symphoeusis at which these states coincide, the number of points will be in those states, the distance between every two of these points being divided into one hundred equal parts, the scale p q of the instrument is constructed. The particular graduation at which, on the top of the column of mercury an inch should indicate the number of inches and hundredths of an inch at which the top of the column of mercury in a barometer would stand at the same time in the same place. But the volume of the hydrogen gas changes in consequence of variations in the temperature of the atmosphere; and therefore a correction, depending on the amount of the variation in the volume of gas for given increments of heat, should be applied to the number of the graduation on the scale of the symphoeusis in order to obtain the true height of the mercury column in a barometer. But, to avoid the trouble of computing and applying this correction, the scale p q of the symphoeusis is made to slide on one side of a scale r which is graduated like that of a thermometer, by communicating different degrees of heat to the vessel C, and observing the points at which the top of the column in B indicates the same number on the scale r as it would express, in degrees, the temperature of the gas; and the scale p q being moved till its index (at 294 inches) coincides with the degree of the scale r corresponding to the temperature of the atmosphere, on the scale of the degrees of a thermometer r attached to the instrument, the graduation on p q corre-
sponding to the top of the column of oil in B expresses the height of a column of mercury in a barometer.

Dr. Robert Gordon, the writer of the article Meteorology in the 'Edinburgh Encyclopedia,' having made a series of obser-
vations for a year, found the indications of the sympometer and those of a barometer, found that the
former stood higher than the latter by quantities varying between 0.03 inch and 0.017 inch, the temperature varying be-
tween 42° and 60°, which was at the same time that, in general, the difference between the indications of the
two instruments increased as the temperature and pressure diminished. The excess of the indications given by one in-
strument over those given by the other may be conceived to have arisen from some inaccuracy in the construction of the
sympometer: but the variation of the excess is not so easily accounted for; it may, however, be supposed to be caused in part
from some absorption between the oil and the gas. It is inferred, therefore, that the indications of the sympometer cannot be relying on accurate measures of the density of the atmosphere; but, since it has been observed that the instrument is frequently affected by changes in that
density, which are too small to be perceived on the scale of a barometer; and since it is well known to be less deranged than the latter instrument by the motion of a ship at sea, it follows that the sympometer has a marked advantage as a marine barometer in indicating the approach of gales of
wind.

SYMPLOCARUS, a genus of plants belonging to the natural order Araceae. It has a succulent spadix, a short
spadix covered with tetrangular flescules. The ovaries are one-celled, with one ovule in each and a minute stigma.
The berries are consolidated, the seeds without albumen. S. fistulosus, Skunk-veed or Skunk-cabbage, has a large
inflorescence with numerous crowded fleshy flbers. The spadix is pro-
cocious, ovate, turged, various in width, spotted, and sometimes covered with dull brownish purple. The spathe is oval, on
a short peduncle covered with perfect tetrahedral flowers, and of the same colour as the spadix. It has hairy
edge-shaped sepal, truncate at the top, and edges inflated; the 4 stamens are opposite the sepals with subulate filaments equal in length to the
calyx. When the spadix decays, the spadix continues to grow,
and every part of the plant, except the sepal, is at the same
level. Within the spathe at the base of each style is a round fleshy seed as large as a pea, white, tinged with green and purple, and invested with a separate membranous coat, and with a prominent
embryo situated in a depression at the top. The leaves spring
up some time after the flowers; they are numerous, large,
pointed, oblong, heart-shaped, and on long channelled petioles.
The plant emits an offensive odour; its tubers are acid, but when dried and powdered, are antispasmodic.

It is considered an excellent remedy in asthma, catarrh, and chronic coughs, and has also been employed in dropsy, rheumatism, and epilepsy.

(Lindley, Flora Medicina.)

TABLE. Since the article Table, P. C., appeared (in 1842) we have kept an eye upon it, with a view to its correction and amplification in this supplement. We were obliged to take much of our article from the description of other writers: though we had ourselves seen a majority of the books we cited. We have since seen many more, and have found several errors in our sources of information; but not more than, in the general laxity of bibliographical description, we were prepared to expect. We shall take the subjects in the same order as in the article above referred to; and when a table is merely mentioned by the author's name in the present article, it will be found in the former one with fuller description.

The restoration of the old numerical type, namely, that in which all the figures except 0, 1, 2, have a head or a tail, and in which the thickness does not vary sensibly from one part to another, was adopted and recommended by the Astronomical Society at the end of 1842; but it had previously been used by Mr. Baily in his detail of the Cavendish experiment, which forms one volume of the Memoirs of that Society. The writer of this article, who first suggested the revival of the old figure (and caused it to be employed in Taylor and Walton's five-figure logarithms, in their reprint of孙row's tables, and in his own work on Arithmetic, before any one else had used it) is decidedly of opinion that one more change is yet wanting, the substitution of dull and rather dark paper for the bright and shining material now in general use, which dazzles the eye too much. Tables should not be hot-pressed, and not even pressed at all. The mischiefs of pressure are two-fold; first, the smooth surface thereby created makes the page a kind of mirror, which has a bright image in one place, whereas the rough paper disperses the light equally in all directions; secondly, the other side of the leaf shows through much more after pressure than before. It is also a mistake to suppose that great blackness in the ink, combined with great whiteness in the paper, is favourable to the reader. Every increase of the contrast, over and above what is necessary to perfect legibility, is injurious to it: jet upon snow would in time destroy the strongest eyes. Of all the things which are meant to be read, a black monumental inscription on white marble in a bright light is about the most difficult: one would suppose, to look at our specimens of expensive printing, that such an inscription was the model which it was intended to imitate, and not, if possible, to surpass. We are satisfied, after many trials and comparisons, that a dull paper, of a whithish brown character, too thick to be seen through, and an ink which is of a dull-black, as it were the very deepest shade of the colour of the paper itself, are the things which are permanently agreeable to most eyes. Those who try it should remember that the first page read is not so good a test as the hundredth.

One of the most legible books we know of is the trade edition of Gibbon's Decline and Fall, &c., in twelve volumes octavo, London, 1820. It is considered by the booksellers themselves to be very badly executed. But printers and publishers are too much in the habit of forgetting that a book is a book and not a line engraving. They look at the page as a whole, and if the individual lines stand out and make their separate existence too perceptible, they pronounce it ugly. Accordingly, the uglier the type we are satisfied, after many trials and comparisons, that a dull paper, of a whithish brown character, too thick to be seen through, and an ink which is of a dull-black, as it were the very deepest shade of the colour of the paper itself, are the things which are permanently agreeable to most eyes. Those who try it should remember that the first page read is not so good a test as the hundredth.

§ 1. Tables of Multiplication.—We were wrong in calling the anonymous table, London, 1775, by the name of Riley. That table, which goes up to 10,000 x 10, is Supplementary to Products. London, printed for J. Plummer. But Riley's table, published in the same year, under exactly the same form, is 'Riley's Arithmetical Tables. . . . London, printed for G. Riley. It is imperfect in all the copies we have seen, especially in those in the possession of 5956. The manner of the same form and size as in Plummer, but the headings and lines are different. We suspect that some writer of more than usual research on the quarrals of authors, of some hunter of old injunction cases, might find something about the history of these two books.

Cedat's Table, Paris, 1797, goes to 10,000 x 10; misprinted 1000 x 100 in our article.

Bretschneider, Produkten-Tafel, Hamburg and Gotta, 1841, goes up to 100,000 x 10.

There is a compression of this kind in finding, for example, the multiples of 62873, the reader must look into the page headed 2800, and there, in one part of the page, opposite to (6) 28, he finds the first three figures, and in another part, opposite to 73, the last three figures. The first part belonging to 628 is repeated twice, once for the cases in which the following numbers are less than 50, and once for those in which they are above it; and an asterisk in the last part of the table occurs when it is necessary to add a unit to the preceding figures. This arrangement brings the table into ninety-nine pages octavo, and is very ingenious: but there is more risk of error in using it than we like. Again, multiplying five figures by one is not so difficult an operation that it need be avoided by using a table which is restricted entirely to three distinct things. Lambert's table (1770), presently mentioned, contains the nine multiples of sin x for every degree, to six figures; and multiples of primes to those of 313.

The Munich table, mentioned in our last article, is 1610, J. G. Herwart, Tabulae Arithmeticae Prouencales * Universales, a folio containing all products up to a thousand thousand.

In the Royal Society's Library is a table by J. C. Centnerswerch, Neu erfundene Multiplications und Quadrat-Tafeln, Berlin, 1825. The earliest table we have seen mentioned is the one given by John Bernoulli (younger), Sexcentenary Table, London, 1779, and Michael Taylor's Sexagonal Table, London, 1786, intended to have the use of logistic logarithms, the former for the first term, and the latter 1°. Both were published by the Admiralty.

§ 2. Tables of division and of prime numbers.—Chenuac's table gives not merely the lowest divisor as stated, but every divisor, for all the numbers under 100000 which are not divisible by 2, 3, or 5. It is accordingly a (larger) and we think a more useful) work than that of Burkhart.

Branker's translation of Rhobinius, mentioned in our preceding article, is of London, 1668, much altered and augmented by D. P.; this D. P. is Dr. Pell. The table of primes, &c. to 100000 is computed under Pell's advice and direction. But there are several places the title of a work of Poll which we have never seen, and which we take from Lepinius: Tabula decem millium difficilium Numerorum, ex uno numero omnium quinque ad centum millium (mile habent difficulitates), English, London, folio, 1666. This looks like a table of prime numbers, and the number of primes under a hundred thousand is about ten thousand. But we must leave it to those who can see the work, if it still exist. Branker's table was reprinted in the

Murhavd mentions the first part of a table (by A. Felkel) of the factors of all numbers not divisible by 2, 3, or 5, from 1 to a hundred million, Venice, 1776. We presume if this work had got as far as either Burkhart or Chermac, we should have heard of it.

§ 3. Tables of squares, cubes, square roots, cube roots, and powers in general. — Perhaps the oldest printed table of squares is that in p. 80 of Pacioli's Summa, &c. [VII, p. C., p. 813; printed in 1494 and again in 1528, which however go very different numbers. — Do in modo di misurare de Distante, &c., Venice, 1564, has squares up to 661. — Magini's 'Tabula Tetragonica,' Venice, 1592, is not a separate work, but a chapter in his work on the planet, the preces numeri give squares up to 10100, but not cubes. It was however published separately, at the same time as the work on triangles, as well as in it: the only difference being that the separate publication has its headings and explanations Italian instead of Latin. The number of so-called books, which are only chapters of other books, is large enough to make a big catalogue.

Lipsius mentions 'Tabulae numerorum quadratorium decies milliomi,' London, 1672, which is Fall's table, though it has not his name. It has also an English title, contains the first ten thousand squares, and also the number of pairs, triads, and quadruplets (in number of figures) with which a square does not finish. Henricus, 'Arithmetica,' Augsburg, 1609, begins with squares and cubes of all numbers up to 360. Hullbronn (p. 627) mentions a tabula Cribiana which gives squares up to 10000000. But for powers of 2, up to 712 power, there are given various tables. John Hill's Arithmetic, of which the seventh edition bears London, 1749, has all the powers of 2, up to the 144th, for the purpose of solving questions about chessboards and horsemen-nails. We also have the title G. C. Sartorius, 'Cubicis tabellae,' Eisenach, 1827.

Maerces, at the end of the tracts on Combinations, London, 1795, has reprinted Hutton's square roots (1)100 to ten decimals, and reciprocals to seven. We believe that Hutton first gave them in his 'Miscellaneous Mathematica,' 4 vols. 12mo. 1775. In Jonas Moore's Arithmetic, 1650, there are the squares and cubes of all numbers up to 1000, the fourth powers up to 306, and the fifth and sixth up to 200. These were reprinted in the edition of 1660.

Roggen mentions 'Art gants neem-teckte,' &c. Desauw, 1755, 8vo., containing the cubes of all numbers up to 100,000, or at least professed in the title-page to give the cube root of every number under a thousand millions of millions: perhaps the cubes went to that of 10,000, with a rule for the fifth figure. And here we may mention that we have been several times in error in our little table giving the extent of large tables, as it ought to do, but the extent which to operations of interpolation will be effective.

§ 4. Pure Decimal Operations. — An anonymous work, 'Tabulae numerorum decimorum, &c.' London, 1622, gives every fraction less than unity whose denominator does not exceed three figures, nor its numerator two, to seven places of decimals. This is a useful table. We may also mention (but not as having seen it) W. F. Wucherer, 'Beyer's zum allgemeinen Gebrauch der Dezimalbruchrechnung,' &c.Karlsruhe, 1795, 8vo.

The oldest table we have found printed in English is in this booke sheweth the maner of measurage of all manner of lande, as well of woodlande, as of lande in the feld, and compting the true number of acres of the same. Newie invented and compiled by Syr Rycharde Benecen Chason of Meesnor in Normando London. Printed in Southwark in Saynt Thomas his hospital by me James Nicolson. There is no date, but Nicolson's dated works run from 1538 to 1558. There is another edition (which omits the tables) printed by Thomas in 1591, and a postscript dated from 1548 to 1575. There are two double-entry tables of the rudest character, for finding the number of acres in a given length and breadth, and for casting up payment at per perch, per acre, &c.

§ 5. A table of the products of numbers; the first part of a bibliographical history of the early part of this subject is so incorrectly given, as well as ambiguously, even by the best authorities, that it will be worth while to collect the several heads, distinguishing the true from the false, and from what we are obliged to take from other sources, putting the name of an authority (of which we have usually two or three) to the latter. Much confusion has arisen from the double meaning of the word publication in the century

following the invention of printing, when it was applied equally to the issue of a printed book and of a manuscript. We are here concerned with the former sense, and it is sometimes difficult to distinguish between the two.

That Albrechtinus [P. C. S.] had substituted sines for Ptolomy's chords,—that he had also used versed sines and tangents,—that he had finished and Regiomontanus's table of chords (issued (in manuscript at least) tables of sines to two separate radical, 6,000,000, and 10,000,000—are historical facts of notoriety. Our question is, what tables were first printed? On the books which Regiomontanus's [Albrechtinus?] hand passed to posterity, and the long list of those which he published and intended to publish (as set forth in his own 'Index Operum, &c.' printed at Nürnberg by himself, his historians, Doppelmayner, Dr. Dürer, W. W., and others) we cannot speak with certainty. We are at variance. In the vague manner in which books and their contents are frequently described by professedly mathematical writers, a good resource is often found in the catalogues of general bibliographers.

The 'Tabulæ Directionum and functionarum' of Regiomontanus were published by himself at Nürnberg (without date, probably about 1476), and were reprinted at Venice in 1485. But we cannot ascertain that either of these contained tables of sines. But Hain (Repart. Bibliogr.), who gives their titles, gives that of the next edition (Augsburg, Ehr. Ratdolt, 1490, &to.) in a fuller manner: from which it appears that there is appended to it a table of sines (mentioned in it), and that Regiomontanus had not given such a table in the former edition: they are, 'Tabella Sinus recti: per gradus et singula minutæ dividit. Ad Tabulæ Directionum Mag. Joh. de Regiomontano, quattuor novem minutæ dividit. This table does not belong to the work, since it follows even the printer's insinuation. Hain also met with it as a separate work; being, as appears from its description in the lisionis, pages, &c. absolutely the same as that which was appended to the Tabulæ Directionum. Accordingly, until something earlier or more definite is produced, we must say that the first known printed table of sines is an anonymous table, to minutes, printed in a quart. date, of 1560, stated (falsely necessaria when it ought to be necessaria) to be necessary to the tables of Regiomontanus, and implying that sines had not then been printed with those tables. From the next-mentioned edition of the Tabulæ Directionum (this we have seen) we should supposes that these tables were to a radius of 600,000, as in that edition, which is of Venice, 1564, 4to. In it we find a minute-table of sines, headed 'Incipit tabella sinus recti,' and with a column containing the differences of the sine. Delambre and others mention Regiomontanus as having given the first tables of tangents in this work under the name of tabula facunda. It is in the edition of 1465, and was reprinted in 1587. It is a table of sines printed with the index; &c. and of sine nomico, Antwerp, 1645. It is to degrees only, and to a radius 100,000, and is a table of cotangents, not of tangents. Delambre mentions an edition of the work, edited by Gaulisius, in 1602, and Nürnberg, 1642, printed out of 13 minutes of this we can find nothing. As yet we have no sines calculated to the new ordinary radius of 10,000, &c. Of these the earliest that we have seen (and we find no earlier ones mentioned) are those of Peter Apian in the 'Instrumentum Geographica, &c.' Ingolstadt, 1533, folio. They are minute-tables to a radius of 100,000, and were reprinted next year in the same author's 'Instrumenum primi Mobilis,' Nürnberg, 1534, folio. Apian states that they are of his own calculation, and this is to us a strong presumption that no such tables had been previously printed; for Apian was a great reprinter of the writings of others at his own press, and very unlikely to have recalculated any table which he knew to exist already. The statement that the work of Regiomontanus on triangles (Nürnberg, 1583, folio) contains tables of sines, is incorrect: we know it from examination of two perfect copies. As we are now contradicting our own previous assertion ['History of Mathematics, P. C. J.'], we will point out how we were misled. Lalande (Bibl. Astron.) says that the first edition of the work, Basle, 1538, has in the title-page 'una cum tabulis sinus.' Now the fact is the tables, who had only, 'Basilea,' no date, known to be of 1561, which does contain tables of sines, took the liberty of presensing that the first edition was the same in contents, title, and place; in all of which he knew itself to be mistaken.

In 1542, Rheticus, the most laborious of all the table computors, made his first appearance as the editor of a work of Copernicus: 'De Lateribus et Angulis Triangulorum,' &c., Wittemberg, 4to. (Weider and Ritter). This contains a
minute-table of sines to a radius of ten millions, being the first-
published seven-figure table. The table which appeared in the
same year, and was by Coicis, P.C., is an abridgment of the preceding; going only to
every ten minutes, and to a radius of 100,000.

In 1641 appeared one of the tables which have obtained
most credit. This is the sixth, and last, of the super-
propositiones Ptolemeii de Sinibus et Cordis, item composition
Tablearum Sinuum per Joannem de Regiomontano. Adjecte
Tabulae Sinuum duplices per eundem Regiomontanum, Nürnberg
1541, folio (Kasnetz, etc.). The two tables of sines are both minute-tables, with radii of 6 millions and of
10 millions. The table of tangents to every degree is repeated
again under the name of tabula facunda.

It has been described in the route of analogy, which suggested to him the formation of a table giving
the ratios which exist between the sides of a right-angled
triangle: by which he was led to the invention of what were
afterwards called sines, to the completion of the trigonomo-
tical canon, and to its arrangement in the form which it has
ever since preserved. His rights in this matter have long
been forgotten; and it is only very recently indeed that the work
which established them has received any notice in modern
times. (See the Notices of the Astron. Soc., vol. vi.
p. 213, and Phil. Mag., June, 1845.) In 1651, the year
following in which he was placed in the Index as a for-
bidden book, he published his book of 'Trigonometrica,' Leipzig,
1640. This is a complete canon to every ten
minutes, and to a radius of 10 millions (or, as we should now
say, to seven decimals) with differences, so arranged that the
resultant errors are on the whole very small, and given in
such a manner as to make it possible for anyone to use the
sheets with facility. This arrangement may be called semi-
quadrantal, as opposed to the older quadrantal arrangement
in which the sines are carried directly from 0 of the Arc.
Accordingly the page of Rheticus has both a head and foot de-
scription, as in modern tables. So completely is he bent on
the idea of a register of the proportions of right-angled
triangles, that he rejects any trigonometrical tables for
the world at large. In his place of the sine and cosine, he has the
perpendicular and base to an hypotenuse of ten millions; in that of the
tangent and secant he has the perpendicular and hypotenuse to a
base of ten millions; in that of the cotangent and cosecant,
he has the base and hypotenuse to a perpendicular of
ten millions.

The same description is adopted in his larger work,
which we shall presently speak.

In 1658 (Delambre) Maurolycus published his edition
of Theodosius, Menelacus, etc. (Messana, 1440), containing
the three tables, that of sines, the tabula facunda, and the tabula
beneficia (as he called the present table of sines). This
table goes only to degrees (except that tangents and secants
0 which were given for 15, 30, 45, 55, and 65 minutes of the last
degree of the quadrant) and is to a radius of 100,000.

Delambre, etc., suppose that these are the first tables of sines which were published, and accordingly attribute the in-
vention to Maurolycus. But we have seen that it is due to
Rheticus and Finck (presently mentioned), who lived close
to these times, states expressly that Maurolycus borrowed
this table from Rheticus.

In 1662 a pupil of Rheticus published a table of sines
to every minute, and to a radius of ten millions. This was
Samuel Eisenmenger (or Siderocrates, as he wrote himself),
in 1660. It is very large, and he was not a copy in the library.

It was, as we find stated in various quarters, a table of sines
in the work on dialling of Hermann Witekind, 'Conformatio
Herculis' which the first edition is said to be of
Heidelberg, 1576, 4to.

The first complete canon to every minute (that of Rheticus
in 1651 being to every ten minutes) was Vieta's 'Canon
Trigonometricus,' published at Adelphi, Paris, 1769, 4to.
We have described this work in the 'Vieta, P. C.,
p. 816, and shall here only make a few additions. Besides the
three title-pages there mentioned, there must have been a
fourth; for in the title of that which Delambre examined
was the motto Durae et quiesust, which is common not
in either of the three seen by us. The work has well obeyed
the direction given: it has lasted in silence, having never
seen other copies or his sines till modern times.

Copies seem to have been rare in Germany; neither Weidler,
Heilbronner, nor Kastner mentions it. Hutton never saw
but his own copy; Montuela (in France!) never saw more than
two, in one of the royal library, and one sold at the
Bouibise sale (but it is not in the catalogue of that sale),
which the historian would fain have bought, but had a curiosi-
ty bid too high.

And this was by the time Montuela's second edition was
written, for by the mention of it made in the first
dition it is clear that the author had never seen it. We have ex-
aminated in London at least eight copies. We have mentioned
(Vieta, P. C.) the complaints which the author had to make
against the printer. The author states that he bought in
many as he could. There are several signs of something odd
having taken place in the printing: and the following is worth men-
tion:—To one of the copies we have seen (as well
as to one of the two that we bought), the printer's
sheet, in correction of a mass of errors in one sheet of the
collection of formulae: this is a separate publication, with the
date (1759) and printer's name on it.

Vieta imitates Rheticus in his method of leading the tables,
but in addition uses the word sine, and calls the table of
tangents facunda, and that of secants facundissima.

He complains that elegant names have not been found, and states
that he gets his denominations from certain tables which
he calls them; it is not often that mathematical tabulators are
called rhapsodists) whom he does not name. In a later work,
the Responsa, etc. (Vieta, P. C., p. 318), published in
1658, he names and objects to the words tangent and secant,
which by that time he had seen. And he proposes to call
the tangents ponsines or oamines, and the secants transversal
lines.

As to the matter of Vieta's tables, it is worth notice
that they must have been made by independent calculation. They
do not exhibit the errors in the last tangents and secants
which appear in all writings prior to the more correct publication
of the French labourers after 1640. It is in the application of the
theory of trigonometry we have not here to speak: we
may simply say that they made the computation of a trigono-
metrical canon a much easier thing than it had theretofore
been. Delambre, etc., declare that this is due to
'Trigonometria Britannica' of Briggs is altogether French in
all that relates to the non-logarithmic part of it. Had he
knew a little more of Vieta, he could have reinforced his
assertion. For the method of solving equations which he
describes (evidently not understanding it) as an obscure
mixture of division and extraction of roots, was the slightly
amended form of Vieta's numerical exegesis, to which we
have referred in EVOLUTION AND EVOLUTION, P. C.,
104. And as, by Gellibrand's account, we trace the com-
merce of Briggs's labours to shortly after the time when
Vieta first published this exegesis, it is by no means an
unlikely conclusion that the power of trisection and quinquese-
tion given by this mode of solving equations, first put it into
his head to construct the table.

Furbach and Regiomontanus had seen the advantage of
adopting decimal tables, though their use of a radius of 600,
which was a remnant of sexagesimalism. It was reserved for
Maurice Breesius to show himself a century behind his time,
by publishing in his 'Metrices Astronomicae Libri Quatuor,'
Paris, 1651, folio, to four places, and in the form of

tables, tangents, and secants, or as he calls them, sines, adscriptes,
and hypothecates. Thus, the radius being 60°, the sine
of 65° 26' is given as 50° 30' 34"; and the adscript and hy-
thecate as 154° 30' 34". Thus, in the sex, meaning 60°.

Accustomed as we are to look upon sex-
gesimal division as sacred to angular and horary measure, we
are apt to forget that the time was when other subdivisions
were rarely used in Europe.
As yet we do not find the modern names of tangens and secund. These were introduced in 1598 by a young man of twenty-two, a lawyer, Thomas Fleet, in his 'Geometricam Rotundi Liber XIV.', Basle, 4to. His part in the matter was quite forgotten, and has been recently revived (see Phil. Mag., May, 1846). He introduces the word with the greatest brevity, and in a way which in other matters would have been judged otherwise than as a proposal of his own, to which it must be added that no earlier use of these words has ever been brought forward. The tables of sines, tangents, and secants, so called, which Fleet published every minute, and to a radius of 10 million. Finck deserves a much higher name than he has got, for the contents of this work alone: there are other writings of his, which we have not seen. He calculated his own secants by a theorem which answers to the formula

\[ \sec \theta = \tan \theta + \tan \left(45^\circ - \frac{\theta}{2}\right). \]

In 1595-6 Clavius published at Rome, in quarto, his edition of Theodosius, to which is appended a treatise on triangles, and a table of sines, tangents, and secants, under those names. They were reprinted in the folio collection of his works, Mayence, 1611. It is clear, on inspection, that these tables are, as far as tangents and secants are concerned, a reprint of those of Finck, in their preliminary theorems, in their arrangement, in their omissions, and in their errors, as well as in the new terms with which they are headed. The names however are as well as we know, not those of Theodosius; both them were Protestants, and Clavius was a Jesuit, high in favour at Rome. Delambre expresses his astonishment that Clavius, in recaptitulating the names of celebrated writers on dialling, should not have used those of Sebastian Münster. The fact was, that Münster followed Luther. We are not quite certain that a greater than Clavius was altogether exempt from thisLaughable weakness. When Vieta suppresses the names of his author, as above noted, calling them merely rhopadoetis, we may almost suspect that he wanted to avoid speaking of Hetricus and Reinhold; for he was very intolerant.

In 1591, Philip Lansberg published 'Triangulorum Geometricarum' Leyden, and in 1602, mint, published 'De Planis Triangulis Liber Unicus,' Venice, 4to. Both these are copied from Clavius: but Magini at least, who goes beyond Clavius in historical reference, willfully supposes the name of Finck.

We at first thought ourselves unable to give a date to the tables of Stevinus, except within a few years, and conjecturally. That he published his Arithmetica in 1585, and that Snell collected his works in Latin in 1605-8, are the facts which are supposed to mark out the known limits of his career. The tables must have been published in 1599, since Vieta's names for the tangent and secant are used; probably, for Vieta's works were of very slow travel. We ourselves believe fully that the Coeometrica, which contains the tables, was published long before it appeared in what is called Snell's collection (in 1608). These tables go to every minute, to a radius of 10 millions, and they are copies of Finck, Clavius, &c. We are informed that recent researches in Belchuan, hitherto, have made it appear that Stevinus was born in 1548, and died in 1620, which puts our opinion beyond dispute.

The mistake about Snell seems to have originated with Gerard Vossius.

In 1588, Nic. Raymar, Ursus Dithmarus, published 'Fundamentum Astronomicum, id est nova Doctrina Sinum,' &c., Strasburg. We cannot make out from the descriptions, whether this work contains tables or not: probably it did.

Who published 'The First English Trigonometrical Table is a point which we have never examined: and we must investigate it in the best way we can from rather scanty materials. We cannot find the word sine mentioned in the works of these (indeed, all the trigonometrical works of either Digges, father or son, or in those of John Dee; nor indeed in any work written in English before Blundeville, except that of Burroughs presently cited. In the 'Alme, seu Catholicae, Thomas Digges, London, 1573, 4to., trigonometrical processes are recorded for which allusion may be made: but it cannot be shown that these were ever applied to the collection of the data. Similarly, Snell, the re-edited edition, was only seventeen years old when the work was published.

The invention is made to Copernicus and Regiomontanus, and the tables of Rheticus are often cited (the ten-minute canon, of 1551). In John Dee's 'Paracentesis Complementi Pro- cæsque Nucleus quidam,' London, 1578, 4to., there are also solutions of triangles, and the tables referred to are those of Regiomontanus with the radius 90,000, before mentioned. But neither of these writers made any reference to any tables published in England. We have examined the libraries of more than one diligent collector of English works of the sixteenth century, without finding anything which at all corresponds, published in England, or even printed in the real inquirer of a complete canon of sines, tangents, and secants.

Blundeville 's 'Exercises,' London, 1594, 4to. (It is said sometimes that 1597 is the date of the first edition, but incorrectly, were commenced, as he informs us, about seven years before. He alludes to Regiomontanus, Copernicus, and Clavius, whom he took as a guide. And he informs us that Regiomontanus is in folio, and that Clavius is in quarto, and published in England, at Rome. We rely much on this in our conclusion that his was the first table: for to mention the form of a book, or the date of publication, is very rare with the writers of his time; and it is most likely that so precise a person would have noticed any previous work of the same kind in his own country. The tables, being copies of Clavius, have almost exactly the same form as those described. It is only that through seven editions at least: the seventh, now before us, has the tables corrected from Pitiscus, by Robert Hartwell, the editor; it is London, 1636, 4to.

It may be supposed, however, that though Blundeville gave the first English canon complete, a table of sines only had been printed four years before. It is at the end of the 'Horo-logiographia, the art of Dialling' by Thomas Fale, London, 1598, 4to. (reprinted in 1599). The sines are to minutes, with a radius of 100,000. This then is the earliest table, but it is of sines only. We have seen that Diggès used sines, but he is a Latin writer, and refers to a foreign table. Perhaps the first writer who used them in English (but still with foreign tables) is the well-known W. Burroughs, in his 'Discourse on the Variations of the Compass,' published in 1581. In the preface he apologizes for introducing rules 'wrought by the English, and sines and triangles wherein they seem strange in our English Tongue,' and he all gives on tables is in the following passage:-- In these examples I have used the abridged table of 100,000 the whole sines, which though it give some ease in the working, yet it is not so exact as that of 10,000,000 of Erasmus Reinholdius. Upto the which, with his Canon fiscundus, answerable to the same, the third Canon of the Hypotheneuses were annexed, we should have an entire Table of Sin, Tangents, and Secants, and a Table of the Table of Tables. This thing, though Georgius Joachimi Rheticus have well begun, and framed it orderly, from ten Minutes to ten: yet is it left very rawy, for such a Table, as the exacte truth of Geometry, and of the precise cause of the plan of the world, which we do not find it easy to use:-- Now let us publish it for the commodite of all such as shall have occasion to use the same for navigatiion and cosmographic. But this table was never published, and accordingly the editor of the edition of 1614 refers the reader to Ralph Handsom's translation of Pitiscus, and the very tables of that work are annexed to the end of the edition of 1614. They are tables to every minute, and to a radius of 100,000. We cannot describe the first edition of Handsom's work, having only seen the second, which is London, 1630, quarto. (Wilson, in the preface to his Navigation, says it was in 1614.) In 1609, John Speidel, afterwards well known in the world of logarithms, began his career by publishing, amongst other things, contains veri necesarie and profitable Tables: viz. A Table of Sines, Tangents, and Secants, &c.' This tract of sixteen pages contains a canon to every ten minutes, and to a radius 1000, with some tables subsidiary astronomy.

In 1610, Arthur Hopton published 'Daculum Geaetasticum, sive Viaticum, or the Geocentrical Sufe.' London, 4to. The seventh book of this is called 'Trigonometria, containing longitudes, latitudes, and other parts of the science, reduced by gallon, with a Canon for the Dimension of trangles.' The canon (from Pitiscus) is complete for every five minutes and

* This is the same as the Blundeville who wrote on Homemanship. A few months ago (it is now October, 1646) a paper was kept in the library, upon proof that Blundeville had described it before 1600.
The rest of the French savans (to whom the subject was particularly interesting, on account of its connection with the
Tables du Cadastre, then preparing) miswere equally interested in the
reception, which might be expected to appear on the separate title-page of the
communefacio. The person who is used to accurate
descriptions of books might possibly, without this warning,
throw away the thin folio we are speaking of, under the idea that it could not be of much importance. The Opus Palatinum: which in fact it is not, though it is an edition of all that was corrected. The 86 pages of reprint are easily distinguishable from the inferiority of paper and type.* The
title-page of the third edition is a sort of octavo...the first page, as follows:—Georgii Joachimi Rhetici
magnum canonum doctrinâ triangulârâ ad decadas secundârum ac praegressâm ad
edicationem de magnis in aliorum codicibus, etc. Recens emendatus a Bartholomei Pictaco Silesio...addita est brevis commonofficio de fabrice et usu ujus Canônica...Canon
bice, una cum brevi commoffacio...etiam separárum ab oppere Palatino renditor. In bibliopoleo Harnichiano. And the commonofficio has a title-page of its own, as follows:—Bartholomei Pictaci Grünbergensii Silesii brevis Perspicâc comunefacio de fabrice et usu magni canônica
doctriinae triangulâriuâ. Exguamni Georgii Joachimii Retici. Necedit Typis Nicolai Schrämeli MDCVII. It thus appears that the date is 1607, which no one has yet noted, except
Kastner, copying an older description, apparently without any distinct separato knowledge of what he was describing. Pictaci published, Frankfort, 1613 (misprinted on two of the
titles 1518, by omission of a C) the folios of the tables of Rhetici by
which himself was enabled to make the preceding corrections, under a long dedication prefixed, as follows:
 Mathematica. The contents, described in modern language, are:—sines to every ten seconds and to fifteen decimals, with first, second, third, and sometimes more demands; those of
the first and last degrees, also to fifteen places, and to every second; the fundamental sines, from which the rest
were calculated, to twenty places: the sines of every 10th, 30th, and 50th second in the first 35 minutes to 22 places (this last table was done by Pictaci himself). Died in July, 1618, very shortly after the publication of the Theatrum.

When we come to reflect, we find that the tables of Rhetici did not make such an epoch in the history of these
things as might have been expected. The ten-minute canôn (1615) which we have described, and of which the memory
was almost lost, introduced the sines, completed the system, and
suggested to Vietâ both the extension and its form. Had Rhetici published his own large table in 1576, it might have been otherwise: but deferred as this publication
was, partly till 1596, seventeen years after Vietâ's Canon had appeared, and partly till 1613, the year before the
first edition of his Theatrum, it turned out that the tables of Pictaci had already been given from other quarters. The next great tables of sines which were produced were the work of Briggs, who
was, as we have seen, exclusively the follower of Vietâ in this part of the business. Briggs was a little more than a tradition, though Vlacq used the last half
of his quadrant in the construction of logarithmic sines. Vossius (1650) knew nothing definite of the tables except the
Thesaurus, and that only in time to insert it in the additions to his work. Sherburne (1675) has not a word of tables. Briggs hardly mentions Rhetici; his biographers not at all. The Jesuit Blancanus omits him as a condemned writer; and it is to be noticed that he was, as to this matter, worse off than Opertiuss himself; and the absolute prohibition against all his writings must have tended to the oblivion into which his name fell. Weidler (1741), writing in the University of Wittenberg, in which Rhetici taught, had not seen the
Opus Palatinum, and knew nothing of what Pictaci had

* The corrected copies of the work, thick or thin, may be distinguished from the uncorrected ones, as follows:—the corrected copies at the running titles of the columns. The uncorrected copy will have, as it ought to have,

Basis Differentia Hypothema

But the corrected copy is not so read like the uncorrected, as to have, it as ought to have,

Hypothema Differentia Basis

† The copies of the two works, the Opus Palatinum, and the Theatrum, which belonged to Delambre, were bought at the sale of his books by Mr. Bagage. The copy of the Theatrum is complete; it is followed by the

Thesaurus, and was bequeathed to Delambre by Lalande. It sold at the sale of the

done. In the Berlin Memoirs for 1786, John Bernoulli (the younger) revived the knowledge of the Opus Palatinum and the Thesaurus of J. L. Rheticus. It had previously come to some statement to the effect that Pitcicus had once received instructions to correct the former. But Bernoulli knew nothing of these corrections, and nothing was known until chance threw a copy of it in the Palatinum in the possession of the late Dr. Brown, who described it in a paper printed in the fifth volume of the Memoirs of the Institute (1804). Delambre gave an accurate account at the beginning of the second volume of the History of Astronomy that Pitcicus had given another account of all the matter, except the corrections of the Opus Palatinum, on which he could only quote from a periodical of 1789.

In 1859 Pitcicus published his own work on Trigonometry, with tables, generally to seven places, and having intervals which may be described in the notation of our former paper as \( \frac{1}{10^{7}} \) (2\( \sqrt{2} \)) \( \frac{1}{10^{10}} \) \( \frac{1}{10^{15}} \) (4\( \sqrt{10} \)).

The edition of 1866, now before us, has of course the corrected tangents and secants. It was reprinted again in 1812, and Dechales mentions a reprint, by Henricus, in 1823.

Pitcicus will always be remembered as the priest who wished that all his brethren were mathematicians,* to make them moral, cold, and benevolent.

Among the non-logarithmic tables, which were published after the invention of Napier turned all the calculators another way, we have mentioned in our former article Schlooten's Table, Amsterdam, 1677, logarithms for the sine of a quadrant. It was followed in 1653 (?) and we know there is an edition of 1672 at Rouen, and of 1683 at Brussels. Editions are mentioned of 1640 and 1664, and also a Spanish edition, Brussels, 1688. John Mytich's Table, Strasbourg, 1602, contain sines, tangents, secants, and tangents and secants, squares, and cubes. Those of Adrian Metius, 1673, give a complete canon, to minutes, to seven decimals. In 1677 Snell published his 'Logarithmianum canonum,' Leyden, containing a complete canon to every minute, and to seven places. Cruger's 'Synopsis Trigonometrica,' Danzig, 1612, gave a five-decimal canon, to minutes. Albert Girard 'Tables des sinus,' i.e. Hague, 1645, had five decimals; there was a Dutch reprint in 1629. Adrian Romanus gave tables (Delambre, Astr. Mod., vol. ii. p. 35) in 1699; they were taken from Clavius. The contents of this paragraph are taken from different sources, and not from the books themselves. We might mention some anonymous tables from various catalogues, but anonymous works of this kind are so rare that we always suspect them.

Austria (1649), the earliest work which has bulk enough to be compared with modern works of the same name, gives nothing more than a canon to degrees and seven decimals, with another to ten minutes and five decimals. The name only of logarithms is mentioned, and an insufficient definition given.

§ 6. We shall now add something to our account of logarithm tables, including a fuller description of a few of those mentioned in our former article. The date and name, where unaccompanied by a title, will serve as a reference to that article.

1614. Napier. It must be specially noted that the logarithms which Napier himself published are not precisely those which are now called Napierian; that is, they are not the simple logarithms to the base \(2.7182818\). As the sines increase, his logarithms decrease. As he uses no decimal point, both his sines and logarithms are integers, the former to a radius of 10 millions. And if \(N\) be a sine and \(L\) the logarithm of it, as they stand in Napier, the equation connecting them is

\[ L = \log_{2.7182818}(N) \]

Delambre proposes to call them Napierian logarithms, and to resolve them into hyperbolic to the modern Napierian or \(2.7182818\) logarithms.

1618. Benjamin Ursinus. The Magnus Canon, besides

* In his preface he says, 'Mansuetudo aetem, bonae Dei, quantum et quam rerum et theologiorum crescentiis! Et quam opacatum est sectae, qua tempora, quae sunt, aetatera, quae futura sunt.' Perhaps the union of the characters of divine and mathematician gives a positive impulse to speak well of the latter, the latter often, in fact, stolid and solemn, and at most, pedantissimum (philosophi) mathematicorum genuinum est mathematicorum. We accept the et alia, for there is no saying how the modern mathematicians might transcribe the first epitaph.

1619. John Speidel. These 'New Logarithms' are the first modern Napierian, or hyperbolic logarithms. The second edition was in 1620, not 1621, as we stated (from others) before we had seen it. The third edition, which was prefixed to it, bears the title-page.

Taking decimals it stands thus—If \(a\) be the sine of an angle, and \(L\) the logarithm to the base 2.7182818 of \(a\), the figures of the Napierian logarithm are found in

\[ a = e^{x} \]

Thus, the sine of 19° 38' is 0.356, very nearly. And we have

\[ \log_{2.7182818}(a) = 0.356 \]
by Montucla, and the history of the book is as follows:

Kepler had stated that Byrgius had invented the very same logarithm as Napier many years before the latter published and that he, Kepler, had informed the author of "Mässen" of his work on perspective (Casels, 1630), says that his brother-in-law and teacher, Justus Byrgius, had, twenty years before that time, made a table of progressions with differences of 10, called a "Mässen", in the Dutch language! This text is quoted in Montucla's history, as reprinted by Rechenkunst," (1783) that this passage of Brummer had led him to look at some old tables which he had bought, and which had lain by neglect. And in these old tables he found that he had certainly the same

See a very full account of them also in the first volume of Delambre's History of Modern Astronomy.

1625. Wingate. "Arithmetique Logarithmique." Under this head, in our last article, we mentioned the difficulty about the date of the book by which Wingate introduced Briggs's logarithms into France. We have since found a copy dated 1625, and we are satisfied, from the date of the "privilegium," that it was printed in 1625. This date is November 4, 1625, and the printing is stated as having been finished April 1, 1625. This edition and that of 1626 are from the same type, except in their title-pages, and a page followed by a paragraph most likely that now printed in 1626, but it is not seen after a further appendix on some points of explanation. It has also additional (perhaps, for the same thing may have been torn out of our copy of 1626) a folding sheet of mean proportional between 10 and 1. The contents are, seven-decimal logarithms of numbers 0(1)10000 with intertext differences; and 0(1)45° logarithms of sines and tangents. This is the introduction of Briggs's logarithms into France; that of Napier was made, as noted, by B. Vincent. But the dates should have been 1619 for the Descriptio, and 1620 for the Constructio.

1626. Henric. In our former article we left this work in doubt. All Delambre gives is from Dechales, who states that Henric wrote on the proportional compasses in 1623 (reprinted in 1818) and on the rule of proportion (which we take to be Guntor's scale) in 1626; and that this last work contains seven-decimal logarithms of numbers from 1 to 10,000,000, composed by Henry Briggs. A Goude. Par Pierre Rammasen. The negligence of a book-binder enables us here to turn up a third or two of our former articles, in a rather singular manner. It will be seen that we have (p. 498) noted Sherwin as stating that he examined his table by one of Vlacq's, in large octavo, printed at Gouda in 1626, of which table we find the number of the tenor, which corresponds in every respect, except that there is no author's name: but one except Vlacq can be mentioned, who was in the least likely to have printed logarithms at Gouda or in about 1626. And we have no doubt is the real first edition of the series of small logarithms called Vlacq's, which will occur several times in our list. Again (p. 498) in speaking of Gellibrand's "Institution Trigonometria," we have noted the table as being from W. Speult, which W. had seen, and which seemed to resemble the description of Gellibrand's tables, which we had not. Now this table, Gouda, 1626, having the title above described (and which we have also seen with the Dutch title and preface), to the table which is always bound up at the end of "Scicographia, or art of Shadowes ... by T. W., Esq., London, 1635, large octavo. That the book was intended to have these logarithms bound in it, and that the book was very rare, we have no title to the logarithms, which look quite like part of the work. But in some copies the binder has not cancelled as required; we have obtained two (since our first article was written) and there is another in the Library of the Royal Society. But in all three copies the title of the logarithms is cut half way up with knife or scissors, as a direction to the binder to cancel it. One of our copies of this Dutch title-page to the tables "Henrici Briggsi Tafel van Logarithmi voor de Ghetallen van een tot 10000. Ter Goude ... 1626.' And the work (though the same impression as before) has a different page, namely "Hendrici Briggsi Tafel ... by T. Wells of Deptford, Esq., London, 1687."

This first edition of Vlacq (1626), as we will call it (being certainly the first small table published under Vlacq's name), contains logarithms to ten decimals; and a complete canon of (logarithms only) to ten decimals and to seven decimals. But the terms cosine, cotangent, co-

1630. Bartusch. The tables which Bartusch published independently of his father-in-law (Kepler) had fallen into oblivion, when Eisenmich found a copy and republished them with Kepler's last tables under the title of "Joh. Keplcr et Jacobi Bartuschii Tabulae mensurae logarithmicae," Strasburg, 1710, 12mo. What the titles and dates of the original works were, we can find only from Lepinus, who gives them as follows:

Whether the first or an original edition do we not know: if so, it was posthumous. The reprint by Eisenmich contains, according to Delambre (Astr. Mod. l. 590), "Naperian logarithms of sines and tangents to ten seconds, but only to five minutes. The reason is that we now (since the first edition) now call logicarithmetic for every second of the first degree, 1° being the first term of the proportion. It is to six figures.

1630. J. Faulhaber, "Ingeniur-schul, Erster Theil," Frankfurt. This work contains logarithms, according to Scheibcl, who does not give a description.

*Women* the first edition of Smarit's tables, hereinafter mentioned, while seems to be wholly unknown to all the modern writers on logarithms. 4, 11.
1833. J. F. Gleditsch, 'Des vollständigen Mathematische Lexiz sweyter Theil,' Leipzig. Here we have squares and right-angled triangles, numbers of signs and targentos 0(1)45°; hyperbolic logarithms, of numbers 0(1)20000; signs, targentos, and secants 0(1)45° to seven decimals; factors of odd numbers not ending with 5, to 10,000.

1843. Cruger, 'Kästner gives Dantzig as the place. The logarithms are Napierian, according to him. 1851. Wing, 'Harmonic Coeleste,' London. The logarithms have separate title-pages, and might, if torn out, pass for separate works. They have the decimal point and are to six decimal places. Signs and targentos 0(1)45° and 0(1)10000, without characteristics. Wing was a much more learned man than his reputation (which is that of an almanac-maker) would imply.

1868. John Newton, 'The Scale of Interest, or the use of Decimal Logarithms.' There is a table of sign and tantages 0(1)10000 arranged in lines of decade, with a separate table of proportional parts.

1863. Vlaqc, 'Table de Sinus, &c.,' Amsterdam. A great many small tables of logarithms bear the name of Adrian Vlaqc. Those before us, which have the same introduction, one in Latin, the other in French, the third in German, have signs, tantages, secants, and logarithms of signs and tantages, to every minute and to seven decimals. Also, seven-decimal logarithms from 1 to 10,000, heading for Arigri briggi Tabula Logarithmica; the year 1692.

1885. Oznamin, 'Tables des Sinus,' &c., Paris. This is really Vlaqc in every particular as to the tables, though his name is not mentioned.

1890. Decahal, 'Cursus seu Mundus Mathematicus.' The first volume has seven-decimal tables; logarithms of numbers 0(1)10000; of signs and tantages 0(1)45°, and the signs and tantages also.

1890. Wm. Leybourn, 'Cursus Mathematicus.' This book has internal evidence of having been written before 1680. Seven-decimal logarithms of numbers 0(1)10000; six-figure logarithmic 0(1)16° and 0(1)16°; signs, tantages, and secants, &c., 0(1)45°; the names costes and secant not used.

1890. John Wing (nephew of Vincent), 'A compleat Body of Surveying, formerly published by Vincent Wing,' London. Five-figure logarithms of signs and tantages, 0(1)45°; of numbers, 0(1)10000.

1764. J. H[arries], 'Table of Logarithms, quarto, in Hisston's salo catalogus.' There is a table of logarithms for numbers increasing in their natural order, &c., London. Six-decimal logarithms of numbers 0(1)10000. The logarithmic part has a separate title, 1764, 'A Triangular Canon Logarithmical,' London. Six-decimal logarithms of signs, tantages, and secants 0(1)45°. As far as appears, this table was got up by J. Seiler and C. Price, mathematicians, and it seems to have of signs and tantages a table to sell their own tables of logarithms as well as their own squares.

1710. John Harris, 'Lexicon Technicum,' vol. ii. This volume contains seven-decimal tables of logarithms 0(1)10000, and a complete canon (including versed sines), 0(1)45°, both natural and logarithmic. There is also a table of proportional parts for every integer from 44 to 420. These tables, except the last, seem to have been taken from Sherwin.

1721. In this year was printed at Pekin, by command of the Emperor Kang-Hi, in Chinese type and in three folio volumes, Vlaqc's logarithmic tables of signs, &c., to ten seconds, and of numbers to 100,000. (Brunez, from Vegas, who had seen it at Vienna.)

1741. Deparcieux, 'Nouveau Traité de Trigonométrie Rectiligne et Sphérique,' Paris. Deparcieux is so much better known by mathematicians, and all of his other writings are neglected. The tables are all to seven decimals (though the decimal point is not used). There are logarithms of numbers 0(1)20000; signs, tantages, and secants, &c., 0(1)0° to 0(1)45°, and 0(1)90° to 0(1)135°; and the tantages and secants are in the table we remember to have seen in which the argument of degrees, minutes, and seconds accompanies the logarithms of numbers. The book is also distinguished by its gnomonical tables, and gives rules for finding the tangents and secants of two angles.

* When a person is distinguished by one particular work, his other, and particularly his previous, writings, even on the same subject, go out of notice. Naturally, this does not apply to the author of this note (from the Memoirs of the Academy) a small work on the elliptic motion and on the figure of the planets, in 1747 (?). See (Lamote, Bibl. Astron. ann. 1842.) And how many biographical accounts of Laplace mention it?

1742. J. F. Gleditsch, 'Des vollständigen Mathematische Lexiz sweyter Theil,' Leipzig. Here we have squares and right-angled triangles, numbers of signs and tantages 0(1)45°; logarithms of numbers 0(1)20000; signs, tantages, and secants 0(1)45° to seven decimals; factors of odd numbers not ending with 5, to 10,000.

1743. Rivard, 'Tables des Sinus, &c.,' Paris, with the official approbation of Clairaut. Seven-decimal logarithms of signs, tantages, and secants 0(1)45°; signs and tantages 0(1)10000, without characteristics. Only decimals of numbers 0(1)20000: all with characteristics and no decimal points.

1770. J. H. Lambert, 'Zusammt zu den Logarithmischem Tafellen,' Berlin. This is a miscellaneous collection of tables and formulæ, containing—Primes, and least divisors of all odd numbers which do not divide by 3 or 5, up to 102,000; first ten multiples of all prime numbers up to 213; primes alone up to 102,000; powers of 2 as far as the 76th, and of 3 as far as the 50th; hyperbolic logarithms, seven decimals, 0(1)1000, and 0(1)010; numbers which divide by 2, 3, 5, or only (except those which divide by 2 or 3 only), up to 10,000; 27-decimal arcs 0(1)1000(20)°20°30°(20)°30°, and for minutes and seconds; five-decimal signs and nine multiples 0(1)39°; seven-decimal signs, tantages, and secants, and logarithms of signs and tantages 0(1)36°; tables for hyperbolic logarithmic and cubical logarithmic logarithms; trigonometric, the only table of the kind we have met with; squares and cubes 0(1)1000; figurate numbers to the 12th order, 30°. To 0(1)1000, 8th decimal power of 5 up to the 11th power; seven-decimal square roots 0(1)100.

There is another edition of this useful miscellany, Liezen, 1798.

1785. Douwe 'Tafellen behelzende de Sinussen ... als mede de Logarithmen,' &c., Amsterdam. A complete minute-can to seven decimal places; followed by logarithms to seven places; versus signs and logarithms on the same scale to 90 degrees; logarithms of numbers from 1 to 102,000; and traverse tables.

1778. J. C. Schütze, 'Neue und erweiterte Sammlung logarithmischer ... Tafeln,' Berlin. Also Ricell's de tables logarithmiques. This title and the preliminary explanations are both in French and German. This is a valuable and original collection. It contains the usual seven-figure tables 0(1)10100: a page of multiples of 434 ... and its reciprocals to 48 places, and powers of 2 ... to 25 places. Wolfram's hyperbolic logarithms of all numbers from one to 2200, and from there to 10000 for all numbers divisible by any single digit, all to forty-eight decimal places; common logarithmic logarithms 0(1)11° and 0(1)11°; signs, tantages, and secants, &c., 0(1)45°; the names costes and secant not used.

1788. J. H. Lambert, 'Zusammt zu den Logarithmischem Tafellen,' Berlin. This is a very accurate work, and we have never met with it. (Octavo.)

1883. Callet, 'Tables Portatives de Logarithmes, publiées à Londres par Gardiner,' &c., Paris. This first edition of Callet, as the compiler of the work which we have just cited, was almost entirely that of Gardiner, who was actually and formally so absurd.

* This table was the work of Lint, Wolfram, of the Dutch artillery, and took two years to be published. It is one of the best collections of tables for the fundamenta of the subject which has been made in modern times. Delambre on theotros, Dutt, and Sandbach, &c., in a number of works, all express envy at the manner in which Wolfram so skilfully, and so many pages elapse before the reader can find out what is wanted. The table has also been used by most probably by most of our contemporaries, but this is Delambre's way, and is often liable to confuse a person who is looking on the surface of things, and not knowing in which place the thing is found from which he is drawing incorrect conclusions, I suppose never mentions it in the third or his remarks, or perhaps casually in the middle, though until such mention is made, it is sure to be very liable to be misunderstood.
mentes et perfectiones dans leur disposition par M. Callet. Callet added as much of each kind of table as would leave no white in his last page, and, from Mouton, completed the single-second table of sines and tangents up to 2°. Here are the tables of Vigne, Fr. Math. Tables, 1807, giving the basic sines and tangents to 10°. Here are those of the University of Göttingen, containing sines to every second, to how many places he does not say; shortly afterwards he sent the tangents. Lalanne gives a hint that the approaching publication of Taylor's logarithms prevented any steps being taken to print those. He also states that there was in the library of the Academy of Sciences a manuscript volume containing sines and tangents of 0° to 11° 59' to 12 figures; we suppose he means to 11 places of decimals. M. Robert's manuscript came into Delambre's possession, and was bought at the sale of his books by Mr. Babbage, in whose possession it now is. It is in two large folio volumes, the figures (to seven decimals) being given in fraction columns. Some corrections of Callet, discovered by means of this manuscript, were printed in one of the Nautical Almanacs.

1784. J. G. Vega, Thesaurus Logarithmorum canonum completus, Leipzig, 1794, folio 3°, and the explanations are both in German and Latin. This is, no doubt, up to this time, the table of logarithms; the one of all others which ultimate reference should be made in questions of accuracy. Its contents are, — a ten-normal table of common logarithms 1 (1) 10000, distributed in the common manner, a decade in each line, with the differences arranged in the same way, and tables of proportional parts for the first three places of decimals. In these, the sines and tangents to 10 decimals, 0 (10) 2° (10) 45°. Sines 0 (10) 12° to 10 decimals. Lengths of arcs to 11 decimals. Wolfram's hyperbolic logarithms above described, reprinted from Schulze.

1808. J. P. Gergonne, Traité d'arithmétique et de l'art de négocier kaufmannischer Rechnungen, Commercial logarithms. The plan is to have logarithmic tables for integers and different sorts of fractions, among which eights, tenths, sixteenths, and sixtieths are conspicuous. But it will not do. Mohammed must go to the mountain. When coinage, weights, and measures, are decimalized, the use of logarithms will follow as a matter of course. It is useless trying to bring logarithms to ordinary fractions.

1799. J. P. Robert and L. Ideler, Nouvelles Tables Trigonométriques calculées pour la Division cyclique du Quart de Cercle, Berlin. Delambre speaks of this table; but wrong, in saying it subdivides the quadrant but minutely as those himself and Borda published. Meaning by 1' the hundredth of the right angle, and 1' being 0°00'00", and so on, he divides the quadrant into 0 (10) 3° (10) 50'; but Delambre and Borda's, which is not given correctly in our last article, is 0 (10) 5° (10) 5° (10) 50' (10) 50'. The Berlin table gives sines and tangents and their logarithms, through the quadrant; the Paris table gives logarithms only. The former has no logarithms of numbers except 0 (1) 1000 and 999980 (1) 1000001, all to 36 decimals.

1823. J. B. Teschemacher, Tables calculated for the Arbitration of Exchanges, both Single and Compound, London. This is a book of commercial logarithms, though the author wisely avoided frightening the merchant by mentioning the word in any part of his book, the one book of logarithms for the exchange between London and each other place: the tables average about a page each. With this limited range, the logarithms are really effectively applied. The sines and tangents are very much simplified. We are fully of opinion that such a work might be very useful.

1806. Thomas Whiting, Portable Mathematical Tables, London. The sine figures logarithms. This book is a striking proof that in the old figure, the reduction of the thickness of the type very much increases the legibility. This is a very easy book to read, and would exactly suit those who want a large print. Attempt at small type.

1809. Ebert, Adrion Vlaq Tabulœ Sinuum, &c. Leipzig. The contents are as before described. This is a new (and apparently the last) edition of Ebert's, whose preface is dated 1790. Besides the contents above described there are squares and cubes of all integers up to 1000.

1809. George Douglas, Mathematical Tables, Edinburgh. A long preface; followed by seven-decimal logarithms arranged in lists from 1 to 10,000, the first 900 pages are the sines and tangents. Two supplemental tables, with the same from 10,000 to 11,000, and from 100,000 to 101,000. A complete logarithmic canon for minutes, to seven decimals. A corresponding canon giving the logarithmic cotangents, sine-compressed sines, the latter continued to 180°. A table to convert sexagesimal into decimals; and logarithms from 1 to 180, to 16 decimals. A different arrangement from the usual one in several respects.

1812. In Zach's Monathliche Correspondence, vol. xxxvi, page 498, Gauss proposed his logarithms for the finding of log (a ± b) from log a and log b [Logarithmica, Gauß's, P. C. S.], with a specimen. He stated that he has got into the habit of using five-figure tables of his own construction. Gauss has given a short review of Pasquich's tables (next mentioned) in the 'Göttinger gelehrte Anzeigen,' 1817, No. 158.

1817. J. Pasquich, Tabula Logarithmico-Trigonometric contracte, Leipzig. Title and explanations in both Latin and German. Five-decimal logarithms of numbers 0 (1) 10,000; sines and tangents 0 (10) 5° 2' (10) 50'; five-decimal logarithms of sines and tangents, with a table of the squares of sines and tangents 0 (10) 45'; Gauss's logarithms [Logarithmica, Gauß's, P. C. S.] ranging as follows: log 0 (0) 1, log 1 (0) 2, ... log 9 (0) 9, and a trigonometrical canon of squares is, we suppose, almost unique.

1817. E. A. Matthesius, Tabula ad expeditorem Calculum Logarithmorum Summam vel Differentiam duarum Quantitatum, Altona. This is perhaps the most extensive set of tables of Gauss's logarithms in existence. It is to seven decimals, and A proceeds as follows: 0 (0001) 2 (0001) 3 (001) 4 (01) 5 (1) 17. 1821. Nordmann, 'Adrieni Vlaq Tabulæ,' &c. The explanations are given in Latin and German. To the contents of Ebert's edition are added square and cube roots to seven decimals for all integers up to 1000. This is called the twentieth edition, which very likely it is; but it was the editor's duty to have stated what the other nineteen editions were.

1821. Westphal's tables, Leipzig, contain Gauss's tables, to five decimals, with proportional parts.

1822. Matthisius, 'Gemeine Logarithmen,' &c., Altona. Stereoptyped. This table has figure logarithms from 0 to 10,000, with a supplemental table of proportional parts, arranged on the two sides of a folding sheet, on canvas.

1823. J. P. Grusso, De queues Logarithmische, &c., Tabulen, Berlin. A school-book. Seven-decimal logarithms 0 (1) 10,000; squares and cubes, square and cube roots 0 (1) 1000; arcs of the circle; logarithmic sines and tangents 0 (10) 5° 4° (10) 50'.

No date, 'stereoptyped,' Moritz von Prasse, 'Logarithmische Tafeln,' edited by Mollweide, and then by Juhn, Leipzig. Five-decimal logarithms of numbers 0 (1) 10,000; of sines and tangents 0 (10) 45° put together in a new way, so as to separate the common figures, as in the logarithms of numbers, and to get five degrees into a double page, sacrificing the differences; Gauss's tables, A having 0 (001) 2 (01) 3 (01) 5 (1) 5; and a modification of Gauss's table, in which log z is the argument, and log (z+1) the tabular result, x going through (002) 2 (01) 3 (01) 5 (1) 5. An edition of Von Prasse was published by Hulsta, at Paris, in 1814; and the last-mentioned table was published separately by Weidenbach, Copenhagen, 1829.

1838. G. B. Airy, 'Appendix to the Greenwich Observations,' London. A table of sines and cosines, with the differences given in, 0, 0, 0, and 0, 0, 0. There is a separate table both of sines and of cosines, each of which is therefore a transformation of the other. And each again is the table from 0 to 0 repeated, with transformation, four times; so the complete set of tables is a transformation of one table. It is to five decimals, without differences.

1838. Anonymous (Useful Knowledge Society). After the first sircle, the following addition was made: — One page,
for example, begins and ends with the numbers 5290 and 5310, and with the logarithms 71767 and 75259. According, at the corner of the page, so as to catch the eye on opening the book, is

| 5290 | 71767 |
| 5310 | 75259 |

in full. This plan ought to be adopted in all tables, instead of the abbreviations which are frequently employed as headings.

1840. (Second edition.) Moritz Büblmann, Logarithische, Trigonometrische . . . . Tafeln, Dresden and Leipzig. Six-decimal logarithms of numbers 0 (1) 10080; logarithmic sines and tangents 0 (1) 45°; sines and tangents 0 (10) 45°; arcs of circles.

1840. Hülse's edition of Vega, Leipzig, stereotyped. This contains Gauss's tables to five decimals with proportional parts, in six columns, the additional three (which contains a peculiar mode of treating the proportional parts) having been also suggested by Gauss. The most recent tirade of this excellent work (1846) contains seven-decimal logarithms of numbers 0 (1) 10080; logarithmic sines and tangents 0 (1) 45°; sines and tangents 0 (10) 45°; angles of decimals; five-decimal Gauss's tables A being 0 (001) 2 0 (11) 8 4 (5) 5, with the proportional parts above alluded to.

1845. Fifth edition of Stieltjes' 'Sammlung von Hülstafeln' (first published in 1822), Altona. This is a well-known and valuable astronomical collection. What we have here to do with is the republication of Encke's four-figure logarithms, 0 (10) 5000; and 0 (4) 10 (10) 45°, and Gauss's logarithms 0 (001) 1-80 (1) 4.

1846. R. Sheepehanks, Tables for facilitating Astronomical Reductions, London (also issued two years before, without title-page and author's name). The most complete of the four-figure tables we know of, and will do for the purpose oftener than our orthodox septenaries are aware of. Logarithms 0 (1) 1000, with proportional parts, in decimals, logarithmic sines and tangents, in decimals, 0 (1) 24°, with proportional parts for 10°, and 0 (1) 1°; table for converting sidereal into mean solar time; logarithmic sines, tangents, and secants 0 (1) 6° (10) 45°; constants for precession; tangents and secants 0 (10) 80° (10) 80°, with a rule for the rest; Bessel's refractions; Gauss's tables, thus arranged, log z as an argument gives

\[
\log \left(1 + \frac{z}{1 - z}\right)
\]

a tabular result, and log \(\frac{1 - \frac{z}{1 - z}}{1 + \frac{z}{1 - z}}\) as another, log z being 0 (001) 900 (001) 2 (1) 4 in the first table, and 0 (001) 1 (001) 3 (1) 4 in the second; log. sin \(\frac{1}{2}\) hour angle, in time 1° (1) 30°; numbers to logarithms 0 (001) 1.

1847. J. C. A. Stöhr, Elemente der Logarithmischen Tafeln zu sieben placent of decimals, containing logarithms of numbers from 1 to 120,000, numbers to logarithms of 0 to 1, logarithmic sines and tangents to every second of the circle, with arguments in space and time, and new astronomical and geodesical tables; Edinburgh, stereotyped. We do not yet know enough of this table to form an opinion. It is printed at the whole expense of the framers, an enterprising officer attached to the Indian survey. The types were cast for the work, and being of the old figure, we wish of course that they had not been so; but we must say that they look better than any existing figure of the old form could have done in so heavy a page, and that also the unity of the type used in logarithms of numbers with that of the trigonometrical ones is a great advantage. It is a most public-spirited undertaking.

Among the titles of tables which we might have said something on if we had seen them, collected from different sources, are those of—John Lauber ete., Leyden, 1828, 8vo.; Loubert Middendorff, Cologne, 1648, 12mo.; Henry Phillips, London, 1667, 8vo.; Instituti Mathematica, London, 1667, 12mo.; Strachan, Witteberg, 1665, 12mo., and Amsterdam, 1700, 8vo.; D. R. Van Meerop, Harlingen, 1671, Chr. Grünberg, Tabellen Mathem., Berlin and Frankfurt, 1690 (oblong form); Chr. Grünberg, Pisanische Mathem., Berlin and Frankfurt, 1700, 8vo.; Chr. Wolff, Magdeburg, 1711, 8vo.; J. G. Leibnitz, Giessen, 1726, 8vo.; Raph. Leibnitz, Harlingen, 1726, 8vo., and supplement in 1748; J. C. Neukommers, Leipzig, 1759, 4to; J. Meinhold Da Mau, Lisbon, 1790, 8vo.

To our old tables of interest we have to add the following. Stevinus, in the 'Practique d'Arithmetique,' appended to his Arithmetic, Leyden, 1634, reprinted by Albert Girard in Stevinus's collected works, 1625, gave the first tables of compound interest and annuities. They precedence the famous tract 'La Disme,' in which decimal fractions were first proposed. And as this Practice being rather have been conceived the name of the Dismes at the end. If rational arrangement had been studied; and the Disme again should have preceded it, on the same supposition; we must infer it to be most likely that the tracts were placed in the order in which they were written. If this be the case, then it is pretty certain that these tables of compound interest suggested decimal fractions, the account of which speedily follows them. They are constructed as follows:

Ten million fractions, as taken as the basic, is what is called it, and a rate, say five per cent, being chosen, the present value of ten millions due at the end of 1, 2, &c., up to 30 years, are put in a column, to the nearest integer. By their sides are the sums of their values, which give the present values of the several annuities of ten million, as follows:

<table>
<thead>
<tr>
<th>Table d'Intérêt de pour 100.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<tr>
<td>10</td>
</tr>
</tbody>
</table>

The rates are from 1 to 16 per cent, and also for 1 in 15, 16, &c., to 1 in 22; or, as the French say, dener quizoiz, dener seize, &c. At the end is a direction to dispense, when convenient, with some of the last figures.

There is thus a virtual use of decimal fractions preceding the formal one. The same thing happens in the tables of Richard Witt, mentioned in our former article, which we believe to be the first English tables of compound interest, and the first English work (except a translation of the 'Disme' of Stevinus) in which decimals were used; the use of them being something more than the virtual use by Stevinus in the Practique. The next English writer who gave tables of compound interest, Robert Butler, in his 'Manual of Interest,' London, 1633, makes a rather more decided use of these fractions than Witt, and uses the phrase decimal fractions, which had then hardly found its way into books. It should be noted that both Witt and Butler give real half-yearly and quarterly tables, as well as yearly ones.

Mr. Pookor, in his Bibliography of Annuities, &c. (Family Explanation . . . of Assurance upon Lives, London, 1842), gives the following works, which we do not remember to have seen:

In Newton's 'Scale of Interest,' mentioned in the list of logarithms, is a set of tables for six per cent, then the maximum legal rate in London, there is here what is elsewhere—a common almanac, with months, dominical letters, and fixed saints' days; having, in lieu of astronomical information, simple and compound interest and discount tables, telling for each day the amount of one pound from the beginning of the year, or the present value for the end.

The first edition of Smart's tables, the original of all our large tables of compound interest, is 'Tables of Simple Interest and Discount,' at 3, 4, 5, 6, 7, 8, 9, and 10 per cent. per Ann.; also tables of compound interest at the same rates, whereby, &c. By John Smart, at the Town Clerk's Office, London: London, 1707, 4to. (duodecimo size). This second edition, of 1726, is as large, compared with the first, as it is possible its author 'John Smart of Guildhall, Gent.' may have become, compared with the subordination at the town clerk's office. The first edition (which we did not know of when we wrote our last article) we find all modern writers knew as little), besides a smaller range of rates, has not the half-years, and has only six decimal places.

The tables of simple interest are also of very little extent. This set of tables was incorporated (probably by printing) in the article Interest in the second volume of Harris's 'Lexicon Technicum,' London, 1710. There was an abridged edition, with some of the rates and of the half-years left out, in November, the table of compound interest for one half-year, &c.
but still to eight figures, 'Tables of Interest, &c., abridged for the use of Schools, in order to instruct young gentlemen in the use of Decimal Fractions,' by John Smith, &c., London, 1750, quarto (octavo size).

Commercial tables of any real power are rendered impossible in practice by the use of shillings, pence, and farthings, except by the extensive use of them very sparingly. If, for instance, the rule for decimating the parts of a pound [Computation, P. C. S.] were well learned and properly used, some of the older tables, which have fallen into disuse, might be revived with effect. Two of the mentioned in our former article will certainly be reprinted when the time comes; Brown's 'Arithmetica Infinita,' and Webb's 'Tables for buying and selling Stock;' the main portion of the former is the first nine multiples of the decimal, which expresses any number of farthings in a pound. Thus, under 7s. 6d. are -3854166... and its multiples up to nine times. The latter has the multiples necessary to find the quantity of stock which answers to any sum of money, and vice versa, at different prices. These are both pocket tables, and their places are supplied at present by works of much greater bulk and less extensive use.

We go a little out of our way to mention Mr. Edward Sang's 'Assurance and Annuity Tables,' Edinburgh, 1841, folio, a most extraordinary work. The author learnt to print that he might set it up with his own hands, and caused the distribution of the sheets extensively, with the free care used in composition. It contains for a single life, and for the Carlisle tables at 3 per cent., every thing. All annuities and assurances, temporary or deferred, or for the whole life, allowance being made for the sub-sequent period; all the yearly risks of such policies; assurances at increasing or decreasing premiums; five-figure logarithms and antilogarithms, &c., &c., &c. And every result has its logarithmic scale worked by its side result for reference. What is so coldly looked at by the assurance offices, those who study the human mind will be at no loss to decide. The typography is so beautiful, the paper and type so luxuriant, that a century hence a copy will have the same beauty of its own life. Persons having the absolute administration of property, as trustees, corporations, &c., are entitled and bound to grant leases for such a period as is deemed necessary to good husbandry; and this period has, by usage, in the ordinary case, been fixed at nineteen years. There have been many questions as to the extent to which persons holding under entail may grant leases, because in many instances attempts have been made in this form to alienate a considerable estate in the property, which have been strenuously resisted by the successors. In the celebrated Queenberry case, leases granted for ninety-seven years, on a grasmun (that is, a sum of money paid by the tenant on entering, like a fine in England), were struck at by the court of chancery, in order to alienate part of the property (2 Dow, 90). In later cases, leases of forty and thirty-one years have been found ineffectual. A lease of twenty-one years is the longest that has been sanctioned in the court of chancery, but even this case has shown that he has an interest in impugning the contract.

Writing is necessary to constitute a lease, although possession during the part that may remain over of a year begun, may be held as a right from suffrance and acquiescence in its commencement. The proper form of the written agricultural lease has been an object of much attention by conveyancers, and there is a considerable degree of uniformity in the practice throughout the country. There are usually nineteen clauses, as follow:—1. The Description of Parties. 2. The Destination, in which the extent to which assigning or sub-letting is permitted or prohibited is set forth, and provision is made for the arrangements in case of the assignee's default. 3. Clause of Possession, describing the subject let. 4. Duration. 5. Reservation, if there be any rights such as that the tenant may sub-let his land. 6. Landlord's Meliorations, containing such obligations to improve the subject as the landlord undertakes. 7. Warrandice, or guarantee of the title given to the tenant. 8. Rent clause. 9. Tenant's Meliorations, setting forth such improvements as the tenant undertakes. 10. Preservation, containing the tenant's obligations to keep the building, fences, &c. in repair. 11. Insurance, in which the tenant becomes bound to insure the building, crops, &c. against the fire. 12. The tenant's right to the reversion is to be a remnant of feudal usages, is now comparatively rare—it binds the tenant to grind his corn at the mill of the over-lord. 13. Management. 14. Bankruptcy, providing in general for the landlord's rights in case the tenant should cause himself to be declared bankrupt. 15. Removal, by which the tenant engages to
erect the premises at the prescribed term. 16. Reference, providing for arbitration of disputes. 17. Mutual Performance, indicating penalties to be paid by the party failing. 18. Rescission of contract. (Ramsden, P. C. S.) 19. Testing clause, containing the formalities of the execution of the contract. Of these, the clause of management is the most important. It is now much doubted how far it is good policy to bind the tenant to the observance of any farming conditions, control of agriculture. In the highly improved districts, where very scientific farming is expected, the tenant is generally more capable than the landlord of estimating the value of improved agricultural methods. Generally means of increasing the produce of the soil, are at present the object of much attention among farmers, and where tenants cannot alter a fixed routine without the risk of a law-suit, an agreement is laid on the practical application of improvements. The landlord's chief interest in any routine being followed, is simply the preservation of the land from deterioration towards the conclusion of the lease. On the subject of the usual provisions, for management, Mr. Hunter says: 'In those districts where agriculture is best understood, the following are the ordinary rules of management during the currency of the lease:—1. White corn crops ripening their seeds shall never be taken from the same land in immediate succession. 2. A certain proportion shall be under turnips or plain fallow every year, and be sown to grass with the first corn crop after turnips or rape. 3. Grass on the chief part of the land shall be removed from the produce of the farm, nor straw nor hay made from the natural herbage, shall ever be carried off the farm. It is sometimes added, that no turnips or rape or hay of any kind shall be made on the poorest or weakest soils. And sometimes required that no less than half of the turnips shall be eaten by sheep on the ground where they grow. 4. If the soil is not such as to admit of being ploughed and cropped every year, it is stipulated that a certain part or proportion shall be always in grass, and that land laid down to grass shall be, before being broken up again, two or more years in pasture. 5. During the first five or six years of a lease, the conditions are sometimes more specializing the tenant to have so much more in fallow or turnips every year, and so much more in grass, and also to leave the farm in a particular shape, so as to admit of the incoming tenant pursuing a correct rotation of cropping from his very entry. Or, 6. What is approved of by some agriculturists, it may be agreed that the lessee shall cultivate the lands according to the rules of husbandry, but with the addition of specific regulations applicable to the four or five last years of the lease. 7. Adherence to the course prescribed may be enforced by conditioning for payment of additional rent in the event of contravention, besides damages, and with a power to prevent further contravention by which purpose reason to power to make a summary judicial application is occasionally taken. Or, 8. Liberty may be given to the lessee to devise from the prescribed course upon payment of an additional rent specified, which may be found to be sufficient to counteract the pecuniary and personal interest, and not liable to judicial modification. 9. In some districts, though seldom in the most improved, there is occasionally a stipulation that the tenant himself reside upon and manage the farm. (1. 363-370.)

(AR. TREATISE ON THE LAW OF LANDLORD AND TENANT, WITH AN APPENDIX CONTAINING FORMS OF LEASES, BY ROBERT HUNTER, ESQ., ADVOCATE, VOL. 8, 1845.)

TENIODES, a family of Acanthopterygious fishes nearly allied to the Mackeralis. The species comprising it are all long flattened fishes, with very small scales. The following are among the principal genera: Lepidotes, tenioid fishes with elongated mottons, a wide gape, projecting under jaw, and strong sharp cutting teeth. The ventral fins are reduced to small scaly plates. The tail is well formed. The Lepidotes argyrotus of the sea and benthic fishing is an example. It is of a bright silver colour, and attains a length of six feet. It is one of the rarest of British fishes.

Trichirrus resembles the last genus in the character of the head, but has neither ventral nor caudal fins, the tail being represented by a long slender compressed filament. The Trichirrus lipsusus of Linnæus, an inhabitant of the Atlantic Ocean, attains a length of more than 12 feet and resembles a beautiful silver riband.

Gymnotus, the Deal fish, has a very small protractile mouth with small teeth. It has no anal fin, and the caudal is considerably depressed. The Gymnotus is not more than four and six feet in length, but does not exceed a table-knife in thickness. An original description of it may be found in Dr. Fleming's 'British Animals'.

Crepala, the Ribbon or Band-fish, is a well known Mediterranean genus. Crepala is short, the gape oblique, and the teeth well developed. The dorsal and anal fins are both long, and reach to the base of the caudal. The ventrals are serpentine developed. The Crepala rubens, a beautiful little fish about a foot long, and of silvery blue tinge, is occasionally found on the southern coasts of Britain.

The genus Lepidotes of Giorni has a short head with a single row of teeth, and a long caudal fin. The caudal fin is distinct, but not prolonged. The Lepidotes alpinus is allied to Gymnura, but has the tail prolonged into a slender filament, exceeding the length of the body.

TEN: TERRIS, a genus of fossil ferns with broad ribbon-like leaves. In the Cotilide series of Yorkshire and Lancashire. (Brongniart.)

TAGORE, DWARAKANKH. [RAMBOURNE ROT, P.C.S.]

TAILZIE, in the law of Scotland, is the technical term corresponding with the English word Entail, which now generally supersedes it in colloquial use, even in Scotland. The early history of Entail law in Scotland in some respects resembles that of England, but in later times they diverged from each other. In Scotland there was no early effort, such as the statute of Westminster the Second (13 Edw. 1.) which was a favourite provision of English lawyers, and which, if there appear to have been on the part of the judges that inclination to permit perpetuities to be defeated by fictions which was shown in England. Devices however of a very similar nature were adopted in Scotland, in order to defeat attempts by holders under entail to use their lands as if they were absolute proprietors. The first and simplest restriction laid on the destined heirs of an entail was in the form of a mere prohibition, against contracting debts which might occasion the attachment of the estate by creditors, selling the property, altering the order of succession, and the like. A provision of this character, called the 'Prohibitive clause,' was however by the entail accomplishing the end; because if a creditor had really attached the estate for debt, or a person had bona fide purchased it, he was in good faith for wresting the title out of his hands, that the proprietor was under a prohibition against permitting such occurrences. A second provision was added, called an Irritant clause, by which any right acquired contrary to the provisions of the entail was declared to be null. Still this did not effectually intimidate the holder under the entail from making efforts to break it, and did not give the next in succession a sufficient title to interfere. A third provision was added called the 'Resolutive clause,' by which the right of the person who contravened the entail to recover his estate was limited to the amount of the suit. It was provided by statute (1685, c. 22) that all entails should be effective which contain Irritant and Resolutive clauses, and recorded by warrant of the court of session in the Registers of Entails, a rule which is not in force in the present day. The law consists of two main clauses containing the Prohibitory, Irritant, and Resolutive clauses. No attempts were made to counteract the Entail system by provisions of a more radical nature. They are not in direct compliance with the genius of the law of Scotland, and it became a permanent feature in the institutions of the country. A sort of judicial war has however been carried on against Entails individually, which has been productive of a vast amount of litigation and strife, has occupied much judicial time, and has tended to place the titles of property in a precarious and doubtful position. An Entail is excluded from the favourable interpretation of the law. The interpretation of its clauses is to be what is termed strictissimus juris. The intention of the frame is never to be contemplated: every blunder is to be given effect to, and nothing is to be explained by reference to the context, if its own meaning as a sentence is doubtful. Thus, in a late case, those who held under an Entail were prohibited among other things from contracting debt to the effect of the estate being attached. The Irritant clause contained the words, 'If the holder shall not perform the premises, by breaking the Tallizie, contracting of debts,' &c. (enumerating other contraventions), it was provided that 'then and in any of these cases, the said venditures, alienations, dispositions, and other attachments, as well as the arrears, debts, obligations, made to the contrar' should be null. It was found that proceedings by creditors to attach the estate for debt were good, because they were not by name enumerated as contraventions, and this that should be null, though they were prohibited, and mentioned among the things which, if
TAL 607  TAL 607

coming to pass, should cause a cumulus. (Dufief's Tractatus v.
Dunkhar, 28th January, 1842, 4 D. B. M. 923.) Some
statutory enlargements have been made on the powers of people
living in the vicinity of the town, and of the younger children: but the system is still productive of great
domestic inequality, and it is to be hoped that in no long
time it will be swept away as an impediment to the improve-
ment of the country and an injustice to the mercantile
classes.

TAJURRAH is a sea-port in Africa, situated at the most
western corner of the Gulf of Aden, in 11° 47' N. lat. and
45° 44' E. long., and is a large town which extends several miles farther west, and is called the
Bay of Tajurrah. The anchorage is of moderate extent, and
large vessels must remain at some distance from the shore.
It certainly, except during the severe monsoon season.
The town lies at the base of a group of hills of moderate elevation,
which run north and south, and are furrowed by narrow glens,
which during the rainy season bring down a great volume of water.
It contains about 500 houses and a population of 1,200
or 1,500 inhabitants. The houses are built of wooden frame-
work, covered with matting. There are only a few stone
houses in the town, and two mosques. As no cultivation is
conducted on the outskirts of the town, the inhabitants are
all principally engaged in the trade in slaves and salt. The
salt is obtained from the lake of Assal (Adol, P. C. S., v. 1 p.
94), and the slaves are brought to the place by the Dallalko,
or robbers of the coast, in large canoes of the type of a canoe
and Shoa. (Aynwimia, P. C. S., p. 20.) These articles go
chiefly to Mocha and Hodeida; to Aden, wool, sheep, goats,
and butter are sent. There is no bazaar in Tajurrah, but the
commerce of the town, which is conducted by the slave and
bead-bearers, is considerable. The local trade consists of
beads, buttons, fish-hooks, and tobacco. Water is plentiful,
but grass is scarce, and fodder for horses is obtained with
difficulty. The climate is very hot; during the last days of
May the thermometer at noon ranges between 80° and 82°,
but the heat is rendered less oppressive by the sea-breeze,
which generally sets in about eleven o'clock of the morning.
Almost all the inhabitants belong to the Dallalko, and are
ruled by a local chief, who is styled Sultan, and is considered
the chief of the whole nation. None of the Danakil tribes pay
obedience to his orders, but they send him annually a present
of two hundred head of cattle and camels. As this town is the
nearest port to Shoa, and the British have entered into a
closer connexion with the sovereign of that country since
their occupation of Aden, it is hoped that Tajurrah will soon
rise to greater importance. The British have also made a
 treaty with the Dallalko and Somalil, and have acquired two
larger islands, situated near the entrance of the Bay of Ta-
jurrah, and a smaller one which lies farther within the bay;
but it is not known if they are actually taken possession of
and settled.

(Isemberg and Kraft's Journals, detailing their proceedings
in the Kingdom of Shoa, &c.; Kirk's Report on the Route
from Addis Ababa to the Red Sea, London, 1841.)

TALBOTYPE. [Photopf Hat, P. C. S.]

TALLOW (French, suif; German, talg; Italian, secco,
sego; Russian, sovo, taponos; Spanish, sebo) is animal fat
[FAT, P. C. S., p. 204] melted and separated from the fibrous
or membranous matter which is naturally mixed with it.
When pure, tallow is white, and nearly tasteless; but the
tallow of commerce usually has a yellow tinge. It is di-
vided, according to its qualities, into various kinds, of which
the best are used for the manufacture of candles, and the
inferior for making soap, greasing machinery, and some other
purposes. Much tallow is used in the dressing of leather.
This fat is also used in the making of candles in this country is of home production, and, according
to a paper on 'Artificial Light from Solid Substances, and the
Manufacture of Candles,' published by Arthur Aitkin, Esq.,
in the Manchester Quarterly Review, 1840, it is stated that
the manufacture of tallow and tallow. candles (part ii. pp. 123-127), is fitted for use by the renderer,
who chops into pieces the fat and meat received from the
butchers, and boils it in water, by which operation the greater
part of the blood is extracted from the skin, flesh, and
beef, to the top, whence it is removed by skimming. The remaining
fat is subsequently squeezed from the membrane by a powerful
press, leaving the membranous matter in the form of a cake, which is cut into smaller pieces, and dried in the sun,
which, when macerated in warm water, softens and swells, and
becomes a wholesome and palatable article of food for
poultry, dogs, and other domestic animals. It is said to be
extensively used in fattening poultry for the market. Dr.

Ure, in noticing this subject in his 'Dictionary of Arts,' &c.,
adores, describes the tallow as 'the watery matter contained
in every cow, horse, or any other animal, which, when
boiled in water, yields a clear liquid, called tallow. The
caucasian, because the fibrous and fatty matter mixed with it
tend to promote putrefaction: and directs that the liquid
be strained through a sieve into a second copper, and
then treated with earth in a boiling teapot."

Almost all our imported tallow is brought from Russia,
where this article is produced in enormous quantities. Kohl,
in his work on that empire, gives a graphic account of this
great production of the country, and how it is brought by
a network of canals, which is very well adapted to the
translation, published in Chapman and Hall's 'Foreign
Library,' 1842, pp. 501-503), we condense the following par-
iculars. — The exports of St. Petersburg, he states, are
estimated to amount to about 15,000,000 rubles (the ruble
being, according to Mowry, C. P. C., p. 325, worth 3s. 1d.)
annually, of which one-third consists of tallow; while the value
of the exports of this article from other Russian ports is prob-
ably about 30,000,000 more. For these 70,000,000,000 of rubles
about 25,000,000,000 of lbra. of tallow is furnished to the rest
of the world, providing the chief supply of soap and candles to
England, France, Germany, Scandinavia, Italy, and the other
countries of Europe; as well as to Spain, where they are
used as a local currency. The tallow so produced is called
Salgans, as they are called, are exclusively in the hands of
the natives of Great Russia, who have their establishments in all
parts of the steppe. They buy the cattle by hundreds and thousands, and all the further supply for
the tallow trade is brought by them to the salgans to be slaughtered; and Kohl states, that if the
season proves tolerably moist, so that the cattle may fatten
well, the speculation is productive, but that a long-continued
drought is ruinous in its consequences, the tallow-bottlers
remaining empty, and the mesre oxen having nothing but their
skins wherewith to remunerate the speculators. After such
a season, he adds, the provender of the salgans usually close
their books, and declare themselves insolvent, having so
seldom possessed of much capital, and generally carry on
their operations with the money advanced by the merchants
of the sea-port towns.'

The salgans, to which the tallow-bottlers usually begin to
drive their oxen in small numbers towards the close of summer,
generally consist of a spacious court-yard surrounded by the
buildings necessary for the manufacture, embracing shambles
for slaughtering the oxen, houses containing enormous boilers
to boil down the flesh, places for salting the hides, and count-
ling-houses and dwellings for the workmen. In the summer of these establishments, even the birds of prey,
which hover about all the year round, attracted by the
nauseous smell, which, however alluring to them, is
described as being infinitely disgusting to a visitor, and evi-
dently distressing to the workmen. The smell is not so
inquieting, as if conscious of their approaching fate, and be-
come so restless as they approach the salgan, that it is often
necessary to drag them to it by main force, notwithstanding
the device of mixing with the herd, as decoys, a few tame
oxen accustomed to the place, and trained to the service.
About a hundred oxen are driven into the court-yard at once,
and of these twenty or thirty are conducted immediately to
the slaughter-houses, where six or eight butchers are kept con-
nstantly at work, in the midst of stench and filth which Kohl
describes as exceeding everything that the mind can imagine.
The business is generally carried on during the rainy season;
and owing to the use of the fat from the edible part of
the whole salgan is soon converted into a swamp of blood
and mud, the smell of which is never removed by the rigours
of the winter or the storms of the spring. It appears also
that the animal skin and hide is considered an artificial manner to occasion much needless suffering to the
beasts.

After the carcasses are skinned, three or four poops of flesh
are cut off from the flank and brisket, for not being fat
meat, there being little fat in those parts of the body; but
owing to the barbarous method of slaughtering, this meat is
so much injured that none but the poor will buy it. The ro-
natured skin, the visceral omentum of the stomach, intestines,
which are given to the pigs (of which a consider-
able number are always kept at the salgan to fatten during the
season), is thrown into the boilers, of which there are from
to six in every salgan, each large enough to contain the
Dash of ten or fifteen ozen. A little water is put into the boiler, to prevent the 'sud' from being too hot, or the feathers, being burned. The fat, as it collects at the top, is skimmed off with large ladles; and before it is quite cold it is poured into the casks in which it is afterwards shipped. The first fat which cools, is the whitest and is a good white, while is quite greasy, which follows has a yellowish tinge. When there are not sufficient casks at hand, the hides of the slaughtered oxen are sewn up, and the tallow is poured into them, 'till, our author observes, the whole assumes this form sometimes like that the animal wore when living. Of those tallow-stuffed oxen, he adds, 'a large number are usually seen standing about the salgans.'

A further degree of fat, but of very inferior quality, is sub-
sequently obtained by subjecting the mass of bones and flesh to fuse to a tough pressed. This tallow, which is rarely exported, is of a dark brown colour, and is used for greasing wheels and for other coarse purposes.

An ox in good condition, it is stated, will yield from seven to eight pounds (350 to 390 lbs.) of tallow, which is generally worth from eleven to fifteen rubles a pound. The fat is always so greatly in demand, that the merchants often pay part of the price for it while the ox are yet grazing on the steppes; and the singular appearance of the salgans is heightened by the number of merchants and their clerks in attendance, for whom the duration of the season, during which the oxen have fattened comes to receive his rent; the workmen for their wages; cattle-dealers to contract for further supplies of oxen, while perhaps some merchant is in a hurry to purchase and advance means, for the oxen to be purchased by them; and 'a colonist comes in to bargain for the fattening of some 200. In the season he receives back walking masses of hog's-tallow, too yellow and coarse for the market, till the grutters have been a little refined by surly good fats. Sometimes a wealthy nobleman, possessing oxen, but no tallow-making establishment of his own, makes his appearance to farm a salgan for a few weeks, which, and the grutters visit the place to buy the raw-material for feeding pigs on the steppes, or to bar-
gain for the hofas and hides. 'The Turkish captains come eagerly to obtain the tallow in its greatest purity at the fountain-head, for tallow so much esteemed by the gourmands of Constantinople to be idol worshipped in enlightening their darkness; in short, however badly death may be at work, there is, meanwhile, no want either of life or battle in the salgans.'

Notwithstanding the nature of the employment, there is always plenty of hands found to seek engagements in the salgans, the wages being high. The workmen usually earn about 75 or 80 rubles per month during the season, which lasts about twelve or thirteen weeks. In the neighbourhood of Odessa, Koli states, there are seven salgans, in which probably 25,000 oxen are killed every year, besides countless uncounted numbers, which are sent away from Nikolaev, Saratov, Kishinev, and other places; besides, they will be found on an equal large scale.

From details quoted in M'Culloch's Dictionary of Com-
mmonwealth, it appears that the merchants of that city divide the tallow which they receive from the interior into white and yellow candle-tallow, and common and Siberian soap-
tallow; the latter, which is considered the best tallow for soap-making, being brought by several rivers from Siberia to the lake Ladoga, and thence to the Neva by the canal of Schlusselburg. An embargo on the export, is appropriated to the reception of the tallow on its arrival, in which it is se-
lected and sorted (or brisk and) according to quality, after which the casks are marked with the quality, the date of the selection, weight of the contents of the barrel or cask. The white tallow is usually brought in conical casks, 22 feet in diameter at the largest and 14 at the smallest end; but the yellow tallow is commonly in casks of the more usual shape. 'Tallow is said to be a clean, dry, hard, and broken, and of a fine yellow colour throughout. The white tallow, when good, is brittle, hard, dry, and clean. The best white tallow is brought from Wurtemberg. This however is said to be better the more greasy and yellow it is. M'Culloch states that 120 pounds of tallow, gross weight (of which the cask is usually about 10 per cent.), make a Peters-
berg candle.' Soap-tallow is stated. 'Soap-tallow is stated. 'Soap-tallow is stated.'

In his account of the candle-manufacture, referred to at the commencement of this article, Mr. Aikin refers to the practice of mixing different kinds of tallow together according to the mode in which the candle is intended. 'We understand, that the various gradations of bleaching are produced by different proportions of the mixture; but it is stated in the article 'Candle, in the 'Encyclopaedia Britannica,' that one-half of sheep's and one-half of bullock's tallow should be used, and that hog's tallow, though it is inferior, is generally used for candles, gutter, give an offensive smell, and produce a thick black smoke; and Dr. Ure states that 'mutton-suet, with a propor-
tion of ox-tallow, is selected for mould candles, because it gives them gloss and convenience. When weighed in the propor-
tions, and cut up into small pieces that it may melt the more readily, the tallow is, according to Aikin's account, put into a boiler with some water, which tends to prevent its becoming too hot, and melted at a temperature of about 90°. Some water is then sprinkled upon it, which has the effect of causing such droops and impurities as may have escaped the skimmer to sink to the bottom, after which the-
clear tallow is let out by a spout into suitable vessels, and when sufficiently cooled, but while yet retaining its perfect transparent fluidity, it is fit for use. Different kinds of tallow melt and retain their fluidity at very different degrees of tem-
perature; the fat which is deploited about the kidneys being, in all animals, harder than that found in the cells of the ox, and especially than the half-offy fat found in the muscles and other soft parts; while the fat of some animals is harder than that of others; but in the case of the tallow when the fat is melted, it is found, and mixed with the wax, that the former is greatly much sooner than that of the ox or horse. Accordingly therefor to the different kinds of fat which may enter into its composition, tallow will be found to vary considerably in its fusibility: but it is necessary for the tallow to be properly applied, and brought to the correct point, though Aikin states that he had seen a boiler full of tallow perfectly fluid at 72°, and even then not sufficiently cooled to be made into candles; nor was this, he observes, considered remarkable; 'whence we may conclude that the same, when made into candles and exposed to the air, loses much of its fusibility.' The author of the article above referred to in the 'Encyclopaedia Britannica,' observes that no water should be mixed with the tallow, and that the tallow must be allowed to cool for two or three hours, before it is ready to use. The wicks, being quite dry, should be imbed, and thus cause the candles to spatter in burning. He adds that in removing the melted tallow from the boiler to the tub or vessel in which the candles are dipped, it may be passed through a coarse horse-

47. This act reduced the duty on about 750 different articles on which the receipts had amounted to about 270,000L. The general principle of the measure was to reduce the duty on raw materials to about 6 per cent., to limit the highest duty on complete manufactures to 12 per cent., and to cut off the duties on complete manufactures to about 20 per cent. The number of articles in the tariff was now reduced to 818. Foreign horned cattle, sheep, goats, swine, salmon, soles, and other fish, and fresh beef and pork, which had been admitted formerly, were admitted on paying a duty under the tariff of 1842. In 1844 the duty on foreign wool was abolished. In 1845 Sir Robert Peel effected further improvements in the tariff by abolishing duties on tea, coffee, and spirits, and on 430 other articles, on which the duty amounted to 390,000L. By this plan of expenses of warehousing are saved [VALENCIANS SYSTEM, F. C.], and a number of troublesome accounts and impediments to business are got rid of, but for statistical purposes the customs department retains the power of examining articles which do not pay duty. The paramount object of the tariff reform of 1845 was to encourage the abundance and cheapness of raw materials of manufacture. In the same year, by an act (8 Vict. c. 7) to repeal the Duties of Customs due upon the exportation of certain Goods from the United Kingdom, the duties on the exportation of coal, culm, &c. are wholly repealed.

Caps. 84 to 94 of the 8 & 9 Vict. are all acts relating to Customs, Trade, and Navigation, and they all came into operation on the 4th of August, 1845. Cap. 84 is 1 An Act to repeal the several Duties of Customs, &c., relating to the importation of Leather. Cap. 87 is 1 An Act for the Prevention of Smuggling, and specifies the acts which constitute smuggling, and the penalties. Cap. 89 is 1 An Act for the Statutory registration of vessels, &c. Cap. 86 is 1 An Act for the Registration of Vessels, &c. Cap. 91 is 1 An Act for the Regulation of the Trade of British Possessions abroad. Cap. 94 is 1 An Act for the Regulation of the Trade of the Isle of Man.

On the 26th of June, 1846, the royal assent was given to an Act which abolished all the other principles of free trade by a total repeal of several important duties, and by a great reduction of numerous others. It is entitled 1 An Act to alter certain Duties of Customs" (9 & 10 Vict. c. 23).

On the same day (June 26, 1846) the royal assent was given to the act for repealing the duties on the importation of foreign corn. It is entitled 1 An Act to amend the laws relating to the Importation of Corn (9 & 10 Vict. c. 22). By this act certain reduced sliding scale duties are substituted for those of 1842, and they are to continue till Feb. 1, 1848, when all duties on the importation and entry for home consumption of corn, grain, and flour, in the United Kingdom and in the Isle of Man, are repealed, with the exception of 1s. per quarter on all wheat, barley, bear or bigg, oats, rye, peas, and beans, merely for the purpose of registration of the quantities imported. The sliding scale duties are: wheat-meal and flour, barley-meal, oat-meal, rye-meal, and flour, pea-meal, and bean-meal to be 4d. for every hundredweight.

The sliding-scale duties of 1842 (5 & 6 Vict. c. 14) are given under Wheat, F. C., p. 305. The duties of 9 & 10 Vict. c. 22 are as follows:

<table>

In 1840 Mr. Porter, of the Board of Trade, in his evidence before the Parliamentary committee on import duties, showed that out of a total amount of 29,962,610L. of Customs duties received in 1838, 17 articles produced 52 per cent. or £21,700,630, and 29 articles produced 26½ per cent. or 898,661.

In 1842 Sir Robert Peel effected some improvements in this system, which were carried into effect by 5 & 6 Vict. c. 14, No. 182.
British possession in America, or of any British possession within the limits of the East India Company’s Charter, into which the transportation of foreign sugar is prohibited, and imported from thence, the duties following:

**C. s. d.**

<table>

TARRANTUSIUS PATERNEUS, a Roman jurist, was Prefect of the importation under Commodus, by whom he was put to death. (Lampredi, Comm. 4.) He wrote four books De Re Militari, from which there are two excerpts in the Digest. He is mentioned by Vegetius (De Re Militari, 3.)

TARTASH TAGH, or TARTASH-I-LING, is the Turkish name for that mountain-system, which, by the Chinese, is called Thang-ling, and on our maps Bolor Tagh or Bolor Tagh is rendered. Proofs of this are to be seen in various distinctions between free-labour and slave-labour are abolished, the former duties on sugar and molasses are repealed, and the following duties levied:

mentioned ranges are separated from each other. This place occurs near 35° 30' N., and between 74° and 75° E. long., between Chitral and Gilgit, where a high mountain-mass, the Tutacone Mutkala, rises to nearly 18,000 feet above the sea-level. About some thirty miles from this point the mountain-mass extends in a north-by-west direction to 40° 30' N., where its northern prolongation is known by the name of Kozur-urt; it lies between 70° and 71° E. long.

This mountain-mass is of great width, occupying the parallels above mentioned all the countries which lie between 70° and 75° E. long. But we are not exactly acquainted with the altitude of the mountains in the plains on the east and west, as these countries are very difficult of access to European travellers, a few of whom only have reached them. A great portion of these mountains appears to be elevated above the snow-line. This is especially the case with an immense snow-region, which occurs between 35° 30' and 36° 30' N., and which goes by the name of Puchikir. It is considered one of the most extensive snow-regions on the surface of the globe. North of this remarkable region is a depression in the range, in the middle of which is a large alpine lake, called Sir-i-kol, in which the river Oxus originates; it runs out from its western extremity. This lake is the first named place it follows the valley of the Sir-i-kol, or river of Kaghz to its source, then turns northward, passing over the crest of the Terek Tagh to Osch, in the valley of the Sir-i-kol, and crossing again the northern prolongation of the Bolor Tagh, it reaches Kound, and caravans pass along this road, and exchange the goods of Chinese Turkistan for those of Bokhara and the other countries of Turan.

(Elphinstone's Account of the Kingdom of Cabul and its Dependencies; Burnes Travels into Bokhara; Wood's Journey to the Source of the River Oxus; and Humboldt's Central Asia.)

TAXATION, LOCAL. There was published, under the direction of the Poor-Law Commissioners in 1846, a valuable work entitled 'The Local Taxes of the United Kingdom, containing a Digest of the Laws with a Summary of Statistical Information concerning the several Local Taxes in England, Scotland, and Ireland.' England includes England and Wales. It is remarked in the Introduction that 'these local taxes are of two kinds: the rates raised in defined districts; and the tolls, dues, and fees paid for particular services or on certain occasions. But those rates only will be here noticed which are authorised by general statutes or the common law: excluding such as derive their origin from special privileges.' The rates are divided into three classes:—I. Rates of independent districts, on the basis of the poor-rate. II. Rates of independent districts, not on the basis of the poor-rate. III. Rates of aggregation on the basis of the poor-rate. No. I. comprehends—1. The Poor Rate; 2. the Workhouse Building Rate; 3. the Survey and Valuation Rate; 4. the Jail Fees Rate; 5. the Constables' Rate; 6. the Highway Light and Litter Rates (three); 7. the County and Municipal Militia Rate. No. II. comprehends—1. the Church Rates (three); 2. the Sewer Rate; 3. the General Sewers' Tax; 4. the Drainage and Enclosure Rates; 5. the Inclosure Rate; 6. the Regulated Pasture Rate. No. III. comprehends—Counties: 1. the County Rate; 2. the Police Rate; 3. the Shire Hall Rate; 4. the Lunatic Asylum Rate; 5. the Burial Rate. Hundreds: 6. the Hundred Rate; 7. the Borough Rate; 8. the Watch Rate; 9. the Jail Rate; 10. the Prisoners' Rates; 11. the Lunatic Asylum Rate; 12. the Museum Rates. Counties and Boroughs: 13. the District Prison Rates.

The following statement is given in the work published under the direction of the Commissioners, as an approximate summary of the present annual amount of the local rate in England and Wales (p. 178):—

The Parish Rates:

Poor-rate, including the Workhouse Building Rate, and the Survey and Valuation Rate.
Relief of the Poor

Other objects

* The 3 & 4 Wm. IV. c. 52, the chief provisions of which are omitted under Sutras, P.C., was amended by 4 & 5 Viz., c. 263.

Some of the taxes are regularly increasing, and the produce of some, as appears from this table, is not known. It is assumed that the Local Taxation of England and Wales may be regarded as about that of the United States. The amount already shown, does not include the sums raised under special or local acts, of the amount of which some no estimate can be formed.

A century ago the poor-rate was about 700,000L; it is now about 7,000,000L. In 1818 it was 9,320,000L. But the sums levied under the name of the poor-rate are expended on various purposes besides the relief of the poor.

Under the direction of the Poor-Law Commissioners contains a chapter on the Local Taxes of Scotland, written at the request of the Poor-Law Commissioners, by J. Hill Burton, Advocate, Edinburgh.

The Local Taxes in Scotland are distributed by Mr. Burton under the following heads:

1. Administration of Justice, which includes Criminal Prosecution, Court-Rooms and County Buildings, Rural Police, Town Police, Prisons.
2. Internal Taxation, which includes Excision Roads, Turnpike Roads, Highland Roads and Bridges.
4. Civic Economy, which includes Direct Municipal Taxes, Petty Customs, Miscellaneous Burdens.
5. Relief of the Poor.
6. The Church and Education, which includes the Church of Scotland Education.
7. Miscellaneous Taxes.

Mr. Burton observes that the money expended on the ecclesiastical establishment and on education, parishes, in some respects, in the nature of a tax. The amount of money annually levied by local taxation in Scotland is not accurately known. The sum of 896,678L is the approximate amount given by Mr. Burton.

The local taxes in Ireland are distributed under the direction of the Poor-Law Commissioners:

1. Grand Jury cess (in all the counties, including counties of cities in Dublin, Cork, and Limerick, which give title to a bishop or archbishop).
2. Poor-rates (in 130 Unions, comprising every townland and denomination of land in Ireland).
3. Lighting, Cleansing, and Watching Rates (in all cities, towns, and boroughs which may adopt the provisions of the statute).
5. Pipe Water Rates (in every city and town, except Dublin and Cork, and Limerick, which gives title to a bishop or archbishop).
6. Parochial Cess (in all parishes, unions of parishes or chaires in Ireland).
7. Rates for deserted children (in all parishes in Ireland, except those in the city of Cork).
9. Rates by Health Rates (in parishes in which the lord lieutenant shall direct officers of health to be appointed).

### TAXY

The amount of annual local taxation of Great Britain and Ireland accordingly amounts to £14,197,046L. But it is observed that if the deficient information were supplied, it would appear that this amount exceeds 5,000,000L. It is observed, does not include the local taxes raised in particular places under special acts of parliament. The sum raised by general taxation in the United Kingdom for the year ended 5th January, 1846, was 51,713,182L. The amount of the local and general taxation is accordingly about 67,000,000L a year. The public expenditure for the year ending 6th January, 1846, was 49,961,412L, of which sum 29,805,572L was paid on account of the Funded and Unfunded Debt. This leaves somewhat under 21,000,000L for the rest of the general public expenditure. Accordingly the present amount of the local taxation, 15,000,000L, is nearly equal to three-fourths of the public expenditure after deducting the paymasters on account of the Funded and Unfunded Debt. It is well remarked in the work from which these facts are derived (p. 100): 'When the Local Taxes are brought under review in this collective amount, it then at once becomes manifest how really deserving of serious consideration are the modes of raising and expending them, so as to secure the most efficient and economical management of a revenue so important: a revenue, indeed, which derives its importance not only from the largeness of its aggregate sum, but from the extent of the property and the number of persons affected by it, and from the numerous and diversified public objects to which it is applied.'

### TAXICORNES

The second family of the heteromorphous coleoptera, in Latrellie's arrangement of insects. They have no common tooth on the inner side of the maxilla and labium. They are all winged insects with nearly square bodies, and a thorax which conceals or receives the head. They have short antennae and legs adapted for walking only. They live in the earth, but are absent of rocks, or other hard stones. This family is divided into two tribes, of which the genera Diaporus and Cossus are respectively the types.

### TAXITES

A coniferous fossil genus of plants from Stonesfield. (Brongniart.)

### TAXOCRINUS

The last generic name assigned by Phillips to the group of Eocrinoids analogous to Taxocretus (Poteroceratium) Egeriata. It has several synonyms. (Morris's Catalogue.)

### TAYLOR, WILLIAM

William, was born at Norwich, in the year 1765. He was the only child of an eminent merchant of that city. He first studied at a Swiss refugee, and afterwards at a Unitarian minister, at Palgrave, a tutor chiefly selected on account of his religious opinions, which were those of Mr. Taylor. He was better known as Miss Alkin, Taylor was indebted for much assistance in his early studies; aided by her sagacious care, he soon acquired a correct knowledge of the principles of English composition, and after life, he was gratified with his obligations to this celebrated woman, whom he styled the 'mother of his mind.' On leaving the house of Mr. Barbauld, at the age of fourteen, he was placed by his father in his counting-house at Norwich, who was desirous that he should succeed him in his large and prosperous business. Shortly afterwards he was sent on the Continent, under the care of one of the partners of the firm, for the purpose of perfecting himself in the French and Italian languages, which were of importance to the proper conducting of his father's business. Before leaving England, he had already evinced considerable facility in acquiring knowledge of languages; and he had been but a short time abroad when his letters to his parents, in English, French, and Italian, at the early age of fifteen, gave the promise of that eminence as a writer to which he afterwards rose. On his return to his native city, he was encouraged by his father, the prosecution of his studies, and the admiration of his parents and friends; and for the two years he remained there, he appears to have given the tone to its Literary circles. A second tour to the Continent was resolved upon; but, he proceeded to Germany, acquiring a familiar acquaintance with its language and literature. A residence of a year with a clergyman at Paderborn was sufficient for this purpose. The influence of his acquaintance in his rise by the taste not only for the literature of Germany, but for the philosophy of that country: a taste...
which ever afterwards characterized his writings. On his second return to Norwich, at the age of eighteen, his parents perceived in him too early, and a taste too decided for literary pursuits, to allow him to devote himself to the mercantile profession. The affluent circumstances of the father, added to the gratification which he expected to derive from the party to which he was about to be admitted, and the high distinction in letters, induced him to forego the strict performance of his project, and to put no restraints to add to his other distinctions that of being a prominent political character. The quiet of the study was now exchanged for the noisy meetings of political debating.

Taylor allowed himself to be enrolled as secretary of a democratic club established at Norwich. His political activity however, so far from interfering with his desire to obtain literary distinction, served as a stimulus to bring his writings before the public, and thus to extend his reputation beyond the narrow sphere of his native place.

A poetical translation of the 'Lenore' of Bürger was the first publication by which he became generally known. This translation, which preceded that of Spencer, still maintained its place among his literary works, and contains some variations from the original; that of the most importance being the liberty he has taken to transfer the scene of the poem, which in Bürger is towards the end of the Seven Years' War, to the times of the Crusades; in this he has been followed by Sir Walter Scott, to whom the public is also indebted for a translation of 'Lenore.' This work was soon after followed by several other poetical translations, which attained a large vogue, such as the 'Survey of German Poetry.'

The particular metre to which he has adapted many of these translations, and a familiarity and too familiar style of expression, have exposed him to some severe criticisms. In the year 1798 he became acquainted with Southey, whose political opinions in early life were similar to his own; an interesting collection of their correspondence will be found in the biography of Taylor, referred to at the end of this article. In one of them he describes his first interview with Sir James Mackintosh and Dr. Parr; and vividly, though not perhaps impartially, delineates their manner and personality.

Severe losses, consequent upon the war of the French Revolution, induced Mr. Taylor to retire from the management of his father's business; a circumstance which enabled him to give his leisure to the cultivation of his literary studies. Magazines and Reviews still continued to be the principal vehicles by which his writings came before the public. As a reviewer, he was remarkable for his close attention and extensive information on the subject he reviewed. Though not profound as a classical or an Oriental scholar, he in a great measure supplied his deficiency in that respect by his intimate acquaintance with the German translations and original works of the poets, and the commentaries upon them. The style, however, of his prose writings was so peculiar, that it was disapproved by many of his readers; and it became a source of constant altercation between Taylor and the writers of the Review. The titles he has contributed to Southey, 'I should say this man's style has an ambitious singularity, which, like chewing-gum, disappears at first, and is afterwards irksome.' He has also, it is said, attacked Shakspeare, 'He often sacrifice[s] felicity to curiosity of expression. With much philological knowledge, and much familiarity among the Shakspearean characters, the author has not the grace of his dialogue, and his allusions mostly pertinent; yet they have both an unsavoury which startles, and which, if ultimately approved, provokes at least an anterior discussion that is unnecessary.' A pleasing feature in the reviews of Taylor is the enthusiasm with which he entered into his subject, but which led him occasionally to hazard assertions which, on cooler reflection, he often disavowed. Thus it is stated that in one of his papers on the prose of Milton, he expresses the conviction that it is superior to his poetry.

In 1802, on a visit to Paris, Mr. Taylor accepted the management of a weekly local paper, 'The Norwich Iris,' after having used his endeavours to induce Southey to undertake it. This paper became the organ of the party to which he belonged; and his success here was not equal to his anticipations, and it was given up after two years. Then he applied himself anew to his reviewing labours, to the changes which had taken place in his family circumstances affording him an additional motive for literary exertion. The Monthly Review, under the editorship of Dr. Griffiths, was the work in which the greatest number of his contributions appeared. In 1806 he gave to the public his version of Lessing's 'Nathan the Wise;' which was severely criticized in the Edinburgh Review. A succession of pecuniary losses which soon occurred, rendered the position of Mr. Taylor's family, if not one of privation, at least of diminished comfort. His adversity, however, was cheered by the kindly sympathies of his numerous friends, and by several unsolicited offers of assistance, which, though not accepted, were sensibly felt and gratefully responded to. At the same time increase of years and premature infirmities diminished his energies, and his later productions have not added to his fame. Among his last works was a collection of short essays on English Synonyms, which, though incomplete and frequently fanciful, are calculated to assist the philological student, and to lay the foundation of a more complete undertaking. The last years of his life were devoted by him to the study of the species and the character to whom he had proved himself a devoted and affectionate son, and by the decay of his mental powers. He died in the month of March, 1838; his remains were deposited beside those of his parents, in the cemetery of the Octagon Chapel at Norwich.

Mr. Taylor's chief claim to literary celebrity consists in his valuable translations from the German; it was through him that the English first became acquainted with the German literature of Germany. If his talents as a poet were unequal to the task of producing such a translation as the Wallenstein of Coleridge, to him at least must be assigned the merit of having been the first in the field, and perhaps to have laboured in it more assiduously than any other English writer. A good translation does not only require a perfect knowledge of the two languages, but also the power of approaching in some degree to the style of the original. Hence in poetical translations it is necessary that the translator should be a poet also. 'We know,' says a high authority on this subject, 'the remark of Denham, that the sublimity of petty evaporation entirely in the transmutation from one language into another; and that, unless a new or an original spirit is infused by the translator himself, there will remain nothing but a 'captito mortuam.'''

'This transmutation must always be those who have approved their talents in original poetical composition.' (Tyler's Essay on the Principles of Translation, p. 573.) These remarks will account for the chief and perhaps only defects of Taylor's translation. 'Memor of the Life and Writings of the late William Taylor, of Norwich, &c., by T. W. Bobbidge, F.G.S., of Norwich, 3 vols. 8vo., London, 1843; Quarterly Review, vol. LXXIII. p. 27-98.'

TECO'MA (from Tehocaxochitl, the Mexican name of the species), a genus of plants belonging to the natural order Bignoniaceae. It has a campasula 5-toothed calyx, a short-tubed corolla with a campanulate throat, and a 5-lobed bicipitate limb, four didynamous stamens with a sterile filament of a fifth, a bilacinate stigma, a siliqua-formed 2-celled capsule having the dissepiments contrary to the valves; the seeds are flat, the flowers distributed in umbels, and the shrubs or scendent plants, with unequally pinnate or digitate simple leaves with terminal panicled yellow or flesh-coloured flowers. They are natives of the Old and New World in tropical and subtropical climates. They are all elegant plants and well worthy of cultivation.}

T. radicans is a climbing glabrous plant with rough rooting branches, its whitish, acuminate leaves, its racemes of flowers terminal corymbose on long peduncles, the tube of the corolla 5 times longer than the calyx. This is a hardy plant in our climate. It is a native of North and South Carolina, of Florida and Virginia. It is planted as a great favourite in this country. It grows against a wall by throwing out roots from its branches in the same manner as ivy. The flowers grow from the ends of the branches in large
bunches, and the tube of the corolla gradually swells out in the form of a trumpet; hence this and some of the species of Bignonia have been called trumpet-flowers.

*T. siams* is a small tree with somewhat tetragonal glabrous branches, bearing acuminate, alternate and glabrous leaves, the racemes terminal simple. This plant is a native of various parts of South America, the West Indies, and Mexico. The roots of this plant are reputed diuretic drugs, and several other species of Tecoma have reputed medicinal virtues. *T. species* is said to be a useful diuretic, also a cathartic. *T. impetiginosa* and *T. ipe* contain large quantities of tannin, and decoctions of the bark are used by the Brazilians as external applications in rheumatism and a gargar in ulcers of the throat. The leaves are mild and are employed in affections of the eyes. In cultivation the species of Tecoma may be treated in the same general way as recommended for the species of Bignonia. (BIGNONIA, P. C. S.)

(Lindley, Vegetable Kingdom; Don, Gardener's Dictionary.)

TEESDA/LIA (named after Robert Tressdale, author of a catalogue of plants growing about Castle Howard), a genus of plants belonging to the natural order Cruciferae and the suborder Angustifoliate. It has a roundish notched pachy, boat-shaped valves, thickly keeled below, narrowly winged above; the seeds two in each cell, the petals either equal or the two outer larger. The species are small annual smooth herbs with stalked expanded vertical leaves. The flowers yellow, with calyx lobes free.

*T. rubicida* is the *T. Herba* of De Candolle. It has unequal petals and numerous leaves spreading on the ground. The stamens with remarkable scales within, the pouch emerging in the lower calyx and the shorter flower in England, France, Germany, Denmark, and Sweden. It is the only British species.

*T. lepidum* is a native of Europe, particularly of Spain. It differs but little in general characters from the former species, there are two varieties of it.

If the seeds of these little annuals be sown on rockwork or in dry sandy places they will scatter themselves and increase rapidly.

(Ton, Gardener's Dictionary; Babington, Manual of British Botany.)

TELEGRAPH, ELECTRIC. The electric telegraph, although it has only begun to attract the attention of the public from a comparatively recent date, has nevertheless not originated in any sudden but happy idea. The possibility of such an application of electrical power has long been imagined; and from the commencement of the present century, the attempts to render one or other of the phenomena of electricity subservient to such a purpose, have been numerous and of various forms. We shall here briefly some of the most remarkable of these inventions, of which any authentic account exists. We have arranged them as far as possible, in their proper order of succession, down to the present time. In the new world, in the form which which is now present in England; omitting those subsequent stages of the invention, which have related rather to the improvement of details, than to the adoption of any new principles of construction.

With this subject the Electric Clock is so far interwoven, that we have introduced a short description of its mode of action.

From the earliest date which we can assign to the existence of an electric telegraph, its essential parts have been the same. These are, the source of electrical power; the conducting material by which this power is enabled to travel to the distant place; and finally, the apparatus by which, at the distant end of the line, the existence of this power, its amount, or the direction of its action is made known to the observer. In the earlier stages of the invention, the investigator and its promoters were confined to the latter of these three essentials; and so long as the illustration of the idea was confined to the lecture-table of the philosopher, or to the select museum, this part just claimed an undisputed pre-emination. But with the improvement and application of the principle to purposes of general utility, there arose the necessity for an equal, nay, almost for a greater degree of attention to the other requisites. We shall, in our brief survey of the history of this invention, how this fact develops itself.

The experiments of Dr. Watson and others, about the middle of the present century, led to the discovery of electrical phenomena which Franklin mentions having been exhibited on the banks of the Schuylkill, at the same period, may possibly have suggested some notions of the conveyance of information, by means of electricity. The earliest authenticated instances of the use of electricity to produce this effect is said to have been that of Mr. Loomond, in 1787. His apparatus was, however, of the simplest possible construction. He employed, as an indicator, a pair of pith balls, which were suspended from one end of a piece of fine insulating wire, the other end of which the operator took his station, provided with an electrical machine. On charging the wire with electricity, the pith balls would exercise mutual repulsion, and diverge from one another; this was the instrument and by the action of some conductor, the balls would collapse. It is evident that certain numbers of successive divergences might be made to denote particular preconcerted signals. No account is, however, preserved of the manner in which the inventor intended to apply these indications. Subsequently to this, the phenomenon of the spark was used for the transmission of signals. It is well known that on the passage of electricity through an interrupted conductor, a brilliant spark of light is seen, at all the breaks in the continuity of the conducting material. This fact is well known in its application to various electrical toys in the present day. We allude to the outlines of birds, animals, or stars, which are formed of small pieces of tinfoil, attached to plates or strips of glass, at such distances asunder, that an electrical charge may be readily passed through the whole. When this is done, the figure becomes luminous for an instant, and the sparks leap across the small intervals between the successive pieces of tinfoil. Were the various letters of the alphabet formed in this manner, upon a table, and connected each one with a distant conductor, we should be able to send visible signals observed visible in a darkened room, by passing an electrical charge through the appropriate wire. This in fact constituted the Telegraph of Reiner, invented in 1794.

A somewhat similar form of apparatus, involving the same principle, was constructed by arranging the several wires in succession, with a single break in each. The various wires bore the names of the different letters or figures, and any required signal was indicated by passing the charge through the proper wire, when the spark visible at the interruption of the circuit would denote the letter to the observer at the farther end.

This was the point to which the invention had progressed, at the commencement of the present century. The discovery by Volta, of the battery which bears his name, forms the commencement of a new era in electro-telegraphs, although no immediate application of the phenomena of the galvanic current appear to have been made. One or two points present themselves for our consideration, before proceeding to the latter period.

In reference to the relative adaptability of the electricity derived from the ordinary machine, and that from the Voltaic battery, to the purposes of electric telegraphs, we may add a few words, in the form which which is now present in England, omitting those subsequent stages of the invention, which have related rather to the improvement of details, than to the adoption of any new principles of construction.

With this subject the Electric Clock is so far interwoven, that we have introduced a short description of its mode of action.

From the earliest date which we can assign to the existence of an electric telegraph, its essential parts have been the same. These are, the source of electrical power; the conducting material by which this power is enabled to travel to the distant place; and finally, the apparatus by which, at the distant end of the line, the existence of this power, its amount, or the direction of its action is made known to the observer. In the earlier stages of the invention, the investigator and its promoters were confined to the latter of these three essentials; and so long as the illustration of the idea was confined to the lecture-table of the philosopher, or to the select museum, this part just claimed an undisputed pre-emination. But with the improvement and application of the principle to purposes of general utility, there arose the necessity for an equal, nay, almost for a greater degree of attention to the other requisites. We shall, in our brief survey of the history of this invention, how this fact develops itself.

The experiments of Dr. Watson and others, about the middle of the present century, led to the discovery of electrical phenomena which Franklin mentions having been
once; or by so nearly completing the circuit, that the electricity may leap across the interval in the form of a spark. When we present ourselves in a circuit by connecting an electrical machine to make a spark from it, the mode of completion of the circuit is less apparent, though the necessity for it is not less absolute. The body in fact forms the communication between the two ends, or poles of a Voltaic battery respectively, no indications of the passage of the electric fluid through either can be found. But if the wires be brought in contact at any point, or if a sufficient pressure be exerted to complete the circuit, the passage of the fluid from one pole of the battery to the other through the extended wires will take place immediately. If this connection be made at any distant point, by an apparatus fitted for such inducements, the direction and amount of the current may be appreciated, as certainly as they could be, were the circuit completed between the battery poles by this apparatus only. To use the words of the late Professor Daniell, the journeys of this force must be in a circle, and the arrangements must be made in such a way, that the impulse may return to the point from which it set out; it must circulate. It will be seen how important were numerous experiments upon the construction of the electric telegraph.

We may now return to the point whence we have digressed at so great a length. In 1807, Sömmering at Munich proposed to construct an instrument for decomposing water by the Voltaic current, as discovered in 1800 by Nicholson and Carlisle. The form of his apparatus was the following:—In a glass trough containing water, thirty-five gold pegs or pins were arranged vertically, this number of pegs corresponding to the letters of the alphabet, together with the nine digits. Each of these pins was connected with a wire, which extended to the place whence the signal was to be received. At the terminations in brass strips, arranged in a frame side by side, like the wires and pins, insulated from each other. Each brass strip bore the name of the letter or figure which belonged to the pin to which it was connected. The operator, when wishing to send any communication, connected the two poles of the battery, with the brass strips bearing the names of the two first letters required. Decomposition of the water in the trough at the distant end, was instantly indicated by the evolution of bubbles of gas, from the two gold pins thus rendered the two electrodes or poles of the battery. The letters forming any communication were to be in this manner denoted in pairs, the inventor ingeniously availing himself of the different quantities of the two gases evolved, to point out the relative position of the letters in each pair. The hydrogen which made its escape in the largest quantity was always employed to indicate the lower; and the lower strip corresponded to the lower. It is incumbent upon us, however, to bear this rule in view in making his connection with the battery.

In 1816, Mr. Ronalds of Hammersmith invented an electric telegraph, in which he recurred to the use of frictional electricity. This telegraph, which was shown to several scientific men, at the date above given, was fully described by the inventor, in a work published by him in 1823. Mr. Ronalds employed the divergence and collapse of a pair of pit-balls as the telegraphic indication, in which respect the principle was the same as that adopted by Mr. Lomond; but to this simple apparatus, a distinct contrivance was appended, which would render the needle more rapid and easy. A single wire perfectly insulated by being suspended from silk lines, or buried in glass tubes, surrounded by pitch, and protected by wooden troughs, was extended between two stations. From the end of this wire were suspended in front of the dial of a clock a pair of pit-balls, so that while the wire was charged the balls would remain divergent, but would collapse into a state of union after the Voltaic current from earth, or with the hand of the operator, was discharged. A person at one end, having therefore an electrical machine, by which he could maintain the wire in an electrified state, and thus become the communer of a signal of divergence; had it of course in his power to give an instantaneous indication to an observer at that farther extremity by touching the wire with his hand, which, discharging the electricity, would allow the balls to collapse for an instant. But instead of merely employing the successive movements of the pith-balls to denote the various signals, Mr. Ronalds added another apparatus for this purpose. Two clocks, very accurately adjusted, so that they had nothing going, carrying, instead of the ordinary seconds hand, light discs, or mosaic letters of the alphabet, the figures, and other required signals were engraved. These discs turned with a regular step by step movement, and when the hand of the watchman in a small opening, sufficient to allow of one letter at a time being seen. As the discs turned round, each letter in succession would be visible through this space; and it is evident that if the clocks were started with the same signal visible, the movement of the discs would bring similar signals into view at the same time. One of these instruments was situated at each end of the communicating wire. The operator who was about to transact business with the person at the other end of his clock until the letter he required was visible, and at that instant discharged the wire. The momentary collapse of the balls at the distant end then would warn the observer to note the letter visible on his instrument, which would form a part of the intelligence to be received. The successive letters or signals constituting any message were denoted in this manner as the clock discs continued to turn round. In order to avoid the necessity for constant attention on the part of the observer, an arrangement was adopted by which a pistol could be fired by the spark at the further end, to summon the attendant to his instrument. Various signals were also concerted beforehand by the use of which arrangements were made for the transmission of any intelligence was lessened. These experiments of Mr. Ronalds were made with the intervention of several miles of wire, carried backward and forward across his grounds, on his own grounds, and his ground.

Mr. Ronalds, in his work on electricity, published in 1823, informs us that an electric clock was constructed in 1815 by Buzengeiger. A very light pendulum was suspended, with its bob or weight midway between two brass balls, forming the extreme ends of a De Luc's Pile. Having been once set in motion, the pendulum would continue to oscillate between the balls, receiving at the end of each vibration an impulsion, from the attraction of the bodies which it had just touched. The upper end of the pendulum was made to cause the revolution of a small ratchet wheel, by means of the alternate action of two catches, or pallets, one on either side of the wheel. To many of our readers the construction and action of the Dry Pile or column of De Luc may be familiar. It may not however be amiss to add, that it consists of many hundreds, or even thousands, of small discs of silver and zinc foil, piled up in regular orders, with the intervention of writing-paper discs between the succeeding pairs. They are then usually enclosed in a glass tube, and pressed firmly together, by means of screw-caps or ends of brass. The ordinary hygroscopic moisture of the air is sufficient to excite weak voltaic effects in the pile, which are manifested by the two ends exhibiting constantly opposite electrical states. The bob of the pendulum in Buzengeiger's apparatus, at the end of the De Luc column, would therefore acquire a small charge, which would be transmitted to the pendulum in the next order, the second pendulum, in the same manner, taking on the opposite charge, and so on in succession throughout the whole pile; in consequence of which it was repelled by this ball, and attracted by the other. These actions, though very feeble, are long continued, and might suffice to maintain a movement of the pendulum for a very long time. This is the principle on which the opticians' windows at the present day, slender frames are often seen revolving, with paper figures of chariots and horses, under the influence of two or more of these Dry Piles.

In 1819, Professor Gersted of Copenhagen made his great discovery of the action of the galvanic current upon a magnetic needle. He observed that when a galvanic current is passed along a wire, placed parallel and near to a magnetic needle, free to turn on its axis, the needle is deflected to one side or the other, according to the direction in which the current is transmitted. He further noticed that the position of the wire, whether above or below the needle, had an equal influence with the direction of the current in determining the side to which the deflection took place. The power of a single wire in causing this deviation of a needle is very small, but when a whole Volta's pile is employed. Truefitt and Schweiger invented the multiplier, as he called it, in which the needle, being surrounded with many successive coils of insulated wire, is acted upon by the joint force of all. This instrument, constructed by Truefitt and Schweiger, has of the most signal use to the philosopher; it

* Ronalds' Description of an Electric Telegraph, &c., p. 49. Translated from the Edinburgh Review, September 2nd, 1815. In the same work (page 171) Mr. Ronalds, quoting the Journal of the Society of Arts of 1821, states that Mr. M. Ramsay at Manchester, and Mr. Brewe at York, had each constructed an Electric Clock, which received motion from a Dry Pile.
enables him by its extreme delicacy not merely to discover the existence of feeble currents, but also to measure their force and direction with extreme accuracy. Under a microscope, this discovery now forms the basis of the Electric Telegraph, which has spread so extensively over England.

Not shortly after this important discovery had been made, Gossard, Arago, Davy, and others, succeeded in rendering iron magnetic, by the passage of a galvanic current through a wire coiled around the iron. It was found that, provided the iron to which the current was applied for any length of time had magnetic property remaining only during the actual transmission of the electricity, and was lost immediately on the interruption of the electric circuit. If the iron which was exposed to the influence of the current was an iron, steel, lead, sand, charcoal, or phosphorus, the magnetic power became to a greater or less extent permanent in it.1

These two principles have, since their discovery, formed the groundwork of almost all the electric telegraphs which have been proposed, and certainly of all which have hitherto been found practicable. Far be it from us, however, to assume that these principles must henceforward bound the inventive genius of men of science, or that no further progress can be made. Much has been already done, but far more, as yet latent and unknown, may be before us.

M. Ampère suggested the employment of the discovery of (Ealing, 1836), and this suggestion was adopted and carried out by Professor Ritchie, in a model Telegraph exhibited by him at the Royal Institution.2 Ampère's plan however was far from possessing the simplicity, so essential in an instrument of that kind, as is generally supposed. Not only were conducting wires necessary, according to his scheme, for maintaining a Telegraphic communication.

M. Schilling also in 1839, following the ideas suggested by Ampère, proposed a similar form of telegraph, in which there were as many of these galvanometers, each with its appropriate circuit, as there were letters or signs to be used in the various communications. The momentary deflection of any one of these needles was quite sufficient to convey a message, with its denoted letter or sign. The same plan, to a certain extent, seems to have been followed by M. Alexander, in his Telegraph, described about the end of the year 1837. In this instrument a distinct needle was employed for the indication of each letter, as in M. Schilling's apparatus, these needles bearing at one end light screens of paper, which concealed from view a letter or figure, until by the deflection of the needle the screen was removed, and the letter brought into sight. M. Alexander however effected one great improvement, in substituting a single return wire, to which every end of all the coils was joined for the several distinct return wires existing in the previous invention of M. Schilling.3 At a later period this latter gentleman undertook a series of experiments, with a view to the establishment of a communication by means of insulated wires, which he thought the mechanical difficulties present in the accomplishment of his design had arrested his progress, previous to his death, which occurred while he was engaged in the prosecution of his investigations. In both of these telegraphs all that was required, in order to convey the indicating apparatus, and conducting wires, was a contrivance by which the connection of the voltaic batteries could be made with any pair of wires in the former, and with any single wire and the return-conductor in the latter of the two inventions. In M. Alexander's Instrument, a set of keys resembling those of a pianoforte, and corresponding to the number of needles, were arranged on a frame or table. One pole of the battery being connected to the return or common wire, the other pole was joined to a plate of metal, or to a trough of mercury, extending beneath all the keys. On depressing any key, the wire belonging to it, which was continued to the end over the battery connection, was brought into contact with the common wire, and thus the whole current would thus flow along the conducting wire, around the multiplier-coil in the distant instrument, and return by the common wire to the voltaic battery. The keys bore the same letters as the needles to which they were connected, so that the operator communicated any letter by pressing down the corresponding key.

In these two instruments no use was made of the power which exists, of determining the deflection of the needle, by applying it to another instrument. Under a microscope, this discovery now forms the basis of the Electric Telegraph, which has spread so extensively over England.

In a telegraph recorded as the invention of M.M. Gossard and Weber, the varied deflections of a single needle appear to have formed the code of signals. From the use of the telescope, however, so readily applicable to a long line of communication. The telegraphic instrument shown in the drawings annexed to their specification, and which was brought into use on the Great Western Railway shortly after the patents were obtained, consist of five needles, arranged with their axes in a horizontal line. The needles when at rest hung vertically, by reason of a slight preponderance given to their lower ends. Each coil was connected with one of these needles, and the ends of the wires united at the other with a common rod of metal, which joined together the similar ends of all the coils. The current was transmitted from the opposite end of the wires (where the resistance is in a good proportion great) to the conductor of the battery. The receiving needle, a second wire being brought into contact with the other pole, the current returned by the rod of metal connecting the coils and the second wire to the battery again. Two needles were used in this manner as plates, the needle as a galvanometer. By this means one or other of the pair of keys belonging to each needle was depressed. Fixed stops were placed on each side of the needles as to limit their motion, and when resting against them, the needles were parallel to two converging lines, at the point of intersection of which, a letter was placed. This was the signal indicated by the movement of the needles. In a similar manner, as before was drawn diverging from the centre of each axis, mutually crossing one another, a number of points of intersection were formed, at each of which was a letter or signal. Any of these letters could be indicated by the simultaneous deflection of any of these needles. The operator's communication could be carried on with rapidity and certainty.

At the same time a plan was recognized, by which the number of wires required for maintaining a communication might be considerably diminished, and at the same time return wire only, there being no needle in connection with this one. One needle could by the use of this wire be deflected by itself either to the right or left, and thus of course each would furnish two signals, in addition to those formed by its simultaneous deflection with any other. The instruments at the two stations were always rendered reciprocating; that is, at each

1 Thomas' Lectures on Heat and Electricity, p. 512.
2 In this and other parts of this article, when treating of the transmission of electric currents, it will be necessary to simplify the description, to represent the electricity as starting from one end or pole only; and, returning after its circuit to the other. Theory however warns us not to allow even this extreme simplification to be carried too far; and, in order to act upon the experiments, to be described in future, it will be necessary to suppose the force developed at once at both ends of the battery, than to any power acting in one direction only.

3 Mr. Crosse is invited to the kind gentleman to the great man, whose profound and successful researches had already prepared the way, to receive it as a project capable of practical application; it is to the talented gentleman whose name is appended that belongs the credit of the discovery, in which he may well claim to share the honor of the great man, whose profound and successful researches had already prepared the way, to receive it as a project capable of practical application; it is to the talented gentleman whose name is appended that belongs the credit of the discovery, in which he may well claim to share the honor of the great man, whose profound and successful researches had already prepared the way.
end of the line were placed an instrument, a set of finger-keys, and a voltaic battery, so that either station could transmit or receive a signal. By a beautiful arrangement, the keys, on being released after depression, were made to return by themselves to the position necessary to enable that which had been the signalling station to become the recipient. By this means messages and answers, or words and their acknowledgments, could follow one another without the necessity for any intervening instrument or arrangement.

The bell or alarm which was to be rung, when the attention of the clerk at the distant terminus was required, was operated by a deflection of power. It was by an attraction exercised by a horse-shoe piece of soft iron, rendered temporarily magnetic by the galvanic current, was made to draw an armature, likewise of soft iron, towards it, and to cause a small bell to ring by connecting a bell. In the second form of alarm, the movement of the armature merely released a detent or catch from a train of clock-work driven by a spring or weight. This clock-work, by the inter-

vention of a scope-wheel and pallets, rang the bell in the manner well known in common alarms.

In the early part of 1833 Mr. Cooke obtained a patent for some further improvements of this apparatus. Of these the most prominent was the mode of introduction of the intermediate apparatus. Before the date of these patents, the two stations at the extremities of a line of telegraph had alone been put in communication with each other; but Mr. Cooke devised means whereby the messages might be introduced between the two terminals, and any intelligence rendered simultaneously visible in all or in any of them, as required. Furthermore any one of these instruments could be placed at the station, or by another to another part only; and by an admirable contrivance, the same mechanical adjustment which limited the connection of any intermediate instrument to one part of the line, placed its bell in the circuit of the other. This intelligence was being transmitted in one direction from an intermediate station, some message of importance were required to be sent from the terminal, or any other station on the excluded side, the end of the line, the current in that instrument was to warn the attendant to restore his instrument to its intermediate position, and thus leave the line clear throughout.

In the same patent were included some important improvements on the mode of protecting and insulating the wires, which were to be laid beneath the earth, in troughs or troughs of wood, iron, earthenware, or other material; and also in the expedients for detecting the exact position of any accident or derangement, without the necessity of uncovering the whole length. Two needles were also shown to be sufficient for carrying on a complete communication with ease and rapidity.

In the course of the ensuing year (1838) Messenger Cooke and Wheatstone, having added a circuit of about one hundred miles to the Great Western Railway, where its capabilities were tested severely. The results of this trial were most gratifying to the inventors, and demonstrated that the understanding, yet delicate and easily induced from a current of galvanic electricity, the question of the practicalities of the electric telegraph, so long at issue among scientific men, was set at rest for ever. Within less than two years from the date of the existence of the invention of Messrs. Cooke and Wheatstone, the severe test of practical application was borne, not merely without lessening the value of the invention, but in a manner which justified increased admiration in those who witnessed the experiments.

We must here go back a little, to take notice of Dr. Stein- heil's telegraph, which was erected between Munich and Bo- genberg. The conductor was a magnet; a pair of metallic bars were placed within an elongated coil of fine wire. These bars were suspended on axes passing transversely across the coil, and in their quiescent position lay parallel to one another and to the straight wire to which they were connected. The ends were ground or sharpened so that when a current was transmitted along the wire, they had a tendency to move in the same direction, remaining still parallel to each other. Against the outer end of each needle or bar was fixed a contact of steel, which when in contact with a magnet, the pencil would continue to trace a straight line as the paper moved onwards; but on momentarily making the circuit with the battery, the armature was drawn to the electro- magnet, and the pen raised by the spring, so as to make an angular mark, like the letter X reversed, on the paper.

These magnets either being joined in groups, by rapidly succeeding completions of the circuit, or they might be separated by a short or long distance, the points at which the magnets were represented by corresponding numbers of angles, and these were combined so as to form all possible numbers. A short space intervening between two or more successive groups, denoted that they were to be taken together, were represented by two or more places of digits; while a longer space showed the actual completion of one number and the commencement of the next. All the necessary words were represented by various numbers, as arbitrary signs, and were arranged

[Note: The rest of the text is not visible in the image.]
dictionary being used for their interpretation. This plan had also been proposed by Mr. Ronalds, to simplify the working of his telegraph.

The plan was erected by Prof. Morse, in 1844, between Baltimore and Washington, a different mode of recording the signals was adopted. The use of the pencil was found objectionable, from its so frequently requiring fresh pointing, and frequently becoming illegible. The arrangement was retained in regard to the paper, but it was made in its course to pass under a roller having a groove around it. The long arm of the lever carried a blunt steel point, standing out from its upper end under the groove in the roller. When therefore the arm of the lever was elevated, by the attraction of the magnet upon the armature, the steel point pressed the paper into the groove, and produced an indentation. If the attraction were momentary, a depressed point was produced; but if the action were continued for a longer time, a lengthened depression was the result, as the paper was drawn on. The combinations of these two kinds of marks denoted the various letters and figures.

In his first instrument, Mr. Morse produced the requisite groups of angles by means of type having as many projecting ridges or teeth as there were to be angles. These being arranged in a frame, as required for the message, made the successive contacts with the battery as they were drawn under a lever or spring. Subsequently however a single key was introduced, by which the longer the circuit might be completed when necessary. The first plan had the advantage of requiring no exertion of memory on the part of the operator, after the message had been set up properly; but nevertheless, the second, in which all depended on the skill and recollection of the person transmitting any signal, was preferred.

In the year 1837 Mr. Davy of London obtained a patent for an electric telegraph. The actual principles of his invention were three: first, the employment with each wire (of which three were to be used) of two magnetic needles, each movable in one direction, but stopped in the other, in a manner analogous to that in Stehlin's telegraph; secondly, the use of a supplementary battery, to effect the registration of the signals, the connection of this second battery being made by the deflections of the needles; thirdly, the method of registering or recording the various communications, by causing the current of the supplementary battery to pass through a ribbon steeped in a solution of iodine of potassium and starch. The salt being decomposed by the current, a blue spot was produced by the combination of the iodine with the starch, and the position of one or more of these spots across the breadth of the ribbon, determined the nature of the signal transmitted. The action of the two needles in each circuit was similar to that of the beam in Dr. Stehlin's telegraph, in respect to their alternate deflections, according to the direction of the current. Instead however of carrying a cup for ink, each needle bore a small metallic arm on its axis, which needle was directly under the circular fixed stop, came in contact with a brass pin or stud, and thus completed the circuit of the supplementary or registering battery. The stud belonging to each needle was connected with a piece of india-rubber tubing, by which the inscriptions was asunder around a light drum. The edges of these rings bore lightly upon the prepared ribbon, as it passed over a metallic cylinder driven by a weight and cord. Instead however of allowing the ribbon to move at a uniform speed wholly independent of the rate of signalling, Davy ingeniously connected the two parts of the apparatus together, by such means that the movement of each needle caused the revolution of the cylinder bearing the ribbon through a small space; so that the successive registrations forming any communication were placed at regular intervals apart upon the fabric. This was done by introducing a small electromagnet into the circuit of the registering battery, so that whenever this circuit was completed an armature was attracted, and one tooth or division of the cylinder released from a catch or pallet. This tooth was divided into squares by transverse and longitudinal lines, in such a manner that each platinum ring pressed upon the fabric, in the centre between two longitudinal lines, while the space through which the armature was moved, at each division, corresponded to one of the transverse divisions. Thus successive squares were brought in turn under each ring, as the ribbon passed onwards, receiving the registrations as it moved. If we now suppose the cylinder to be connected with the metallic cylinder bearing the cloth, and the other with the axes of all the magnetic needles, the action of the apparatus will be readily rendered apparent. When a current was transmitted from the communicating station, so as to cause the deflection of the first needle of the first wire, the second needle of the same wire then being pressed against (its stop and fixed), the arm of this needle coming in contact with the brass pin or stud, would complete the supplementary circuit, thus allowing the current to pass through the upper arm of the second needle to the registering battery, in connection with the needle axis, it would pass from the axis of the deflected needle along its arm to the brass pin, thence to the first platinum ring (or radius); then through the other needle (second course) to the metallic cylinder, and to the pole of the battery, joined thereto. When the current from the signalling station reached the detector, the second, or parallel supplementary circuit formed with the second platinum ring, and so on with the others. After each signal the ribbon would be advanced one division, so that the successive registrations would take place in succeeding transverse divisions of the fabric. The person who is to communicate has an apparatus, in which, by depressing different keys, he can transmit the electricity in one or other direction through any wire, making it return either by a separate wire or by the earth; or he can employ another of the signalling wires to return the current. In the first case, he would produce a single spot on the ribbon from one ring only; while in the second, spots from two rings would be produced, the direction of the current being determined by the various simple and combined indications, a sufficient number of variations to express the necessary letters and signs could be obtained.

In the year 1840 Professor Wheatstone patented his electro-magnetic telegraph, in which the indicating power was the magnetisation of soft iron by the electric current. The object of the invention was to produce, by excitation and demagnetisation of the magnetic particles of soft iron, certain definite and definite movements of rotation, in dials or indicators; by which movements signals might be given, of various kinds and in various modes. The first part of the apparatus was a semicircular plate composed of a disc of wood, turning horizontally upon a pillar or axis, has its circumference divided into equal spaces, alternately filled up with metal or ivory. The metal divisions communicate with the central column, and through it with one pole of a battery, of which the other pole is connected with the return wire or with the earth. Against the circumference of the disc rests a spring, from the foot of which proceeds a wire going to the line or long conductor. As the disc is rotated from its centre, the spring rests alternately on metal and ivory, and were there no break in the circuit at the distant station, the current from the battery would be transmitted or intercepted. The operation of the apparatus according to this principle is placed a letter or figure, so that by bringing one letter after the other opposite to a stop fixed near the disc, the galvanic circuit would be opened and completed alternately with each succeeding letter or figure. Away turn of the disc, which is provided with spokes or arms radiating around its upper surface: The telegraph which is operated upon by this Communicatory, possesses great simplicity both in its principle and construction. One of the main features of the apparatus is that the voltaic magnet is placed a small armature of soft iron. When the iron is rendered magnetic the armature is attracted to it, but on interrupting the galvanic circuit the magnetism of the iron ceases, and a small revolving spring throws the armature back to its original position. The armature itself turns on an axis, which carries a pair of pallets, making into the teeth of an escamplon wheel. In the instrument first constructed according to this patent the recurrences of the attraction and release of the armature actually formed the motive power of the machinery, the two pallets alternately removing the moving escapement wheel, and the pallets, actuated as above, merely holding the cam that controls the movement of the clock. In either case the object was the same, that is, to communicate to a light paper or mica dial, bearing letters around its circumference, a step by step motion, wholly under the control of the current of electricity, so that the operator might bring any figure or letter on the dial to a small opening in a screen, through which it would be visible to an observer. The number and order of the signals upon the paper disc corresponded with those on the Communicatory previously described. Supposing for instance that the letter A were
opposite to the fixed stop in the Communicator, and that the same action which brought the various things into the presence of the telegrapher; if while in this position the spring of the telegrapher rested on an ivory division of its circumference, no current would pass from the battery. But if the commutator resting on an ivory division, similar to the strife of the escape-wheel pass, and the following signal B would appear through the opening in the screen. The movement to C on the communicator, breaking the circuit, would release the armature of the type-disc, and the cylinder did not turn on a simple axis, but on a screw; so that the words of any communication were arranged in spiral lines around it. When the paper was unwrapped, to be replaced by a fresh piece, the message would be found printed in slightly sloping lines from one side to the other. The action of this instrument was very perfect, and it appeared to possess every requisite which could be demanded in a registering telegraph. There were no obvious impediments to its being brought into use, in the increased cost of the apparatus, and the slowness with which signals would be rendered, as compared with the needle instrument.

Towards the end of 1840 Mr. Bain, in conjunction with Mr. Barwise, patented a clock which was to be set in motion by the pressure of the inventors to employ the magnetic power of the pendulum, in conjunction with the pendulum of a clock, at the end of its oscillations, in the following manner:—An electro-magnetic coil formed the bob of the pendulum, and its movement was connected with the end of two permanent magnets, when at the two extreme points of its swing. On reaching these points, the pendulum itself, by coming in contact with a slender spring, completed the circuit of the galvanic current through the coil, in such a manner that the end of the coil then nearest to the magnet on the side to which the pendulum had oscillated, was momentarily endowed with the same polarity of the coil and magnet, and the former, being free to move, recoiled from the latter with a small impulse, sufficient to carry the pendulum to the opposite end of its oscillation. The same effects then took place, in respect to the other fixed magnet at that side. A small force was thus communicated to the bob of the pendulum, at each extremity of its arc, which was sufficient to maintain its vibrations undiminished; and at the same time to put in motion, by means of the ordinary arrangement of a scape-wheel and pallets, the works of the clock acting upon the minute and hour hands. By causing the circuit to be complete by the passage of the current through the similar coils of other instruments at distant stations, connected by appropriate wires, a series of such clocks might be made to work together with absolute accuracy.

In July, 1841, Mr. Bain exhibited at the Polytechnic Institution in London an electric printing telegraph, and in the following year he proceeded to patent an improved form of the apparatus. The essential principles of this contrivance are two. First, the employment of type, mounted on the periphery of a disc or wheel, capable of revolving with its edge carrying the type very near to a cylinder covered with white paper, between which and the type-wheel a piece of transferring paper or ribbon was placed. The cylinder had a small movement in a spiral direction communicated to it, after each impression of the type.

The action of this part of the apparatus will be readily understood, from the brief description of the printing telegraph of Professor Wheatstone, already given. It is only necessary to particularise, that in Mr. Bain's machine the type were arranged on the edge of the disc or wheel, radiating from its centre; and that the printing of any one upon the cylinder was affected by the movement forward of the entire type-wheel and its axis, by a crank and connecting gear in the printing train. The end of the paper, having been struck down by the printing-hammer, is impressing a signal. The second principle is that of the use of two clocks at the same time, to perform the communication, one by transferring a uniform motion. These clocks, having been adjusted to exactly the same rate, and being started from the same signal, would bring continually, at each station, similar type opposite to the paper cylinders at the same moment. The
in action of this portion of the apparatus is exactly analogous to that of Mr. Ronalds, already described. A hand or index revolving on a dial in front of the machine, at the same rate as the type-wheel, indicates to the operator the signals which are to be printed out for printing in copper the own instrument, and therefore, if the clocks go exactly together, in a similar position in his correspondent's instrument from this hand of returning in contact in its revolution with a pin, placed by the operator opposite to any signal that he wishes printed, completes the electric circuit at this moment, and by so doing stops the type-wheel, and thus enjoying true at each station. A similar signal, having thus been impressed on the cylinder at the two ends of the line, the operator removes the pin, and replaces it opposite the next signal he requires to send. The moment the pin is removed, and the circuit therefore broken, the hands and type-wheels at each station resume their revolutions, which are again checked by the contact of the hand and pin as before.

Mr. Bain's single-index telegraph, which was the instrument proposed by him for practical use, consisted of two hollow cylindrical coils of wire, placed horizontally a short distance apart, with their axes in the same line. Between them a small bar magnet was fixed across a delicate spring, which in free passage through the dial-plate of the instrument, and was turned up to form an index. The two coils were connected, so that an electric current entering from the line wire would pass through both of these, and as the bar magnet would be acted on towards one coil, while at the same time it would be repelled by the other. These actions tended to carry the magnet around the axis, as far as the spring to which it was attached and a fixed stop would allow it to move as a wheel. The reversal of the current inverted the effect of the coils, and the magnet would then pass to the other side. The combinations of these two movements represented the two separate letters and signals, being denoted to the observer by the index on the dial of the instrument. The movement of the index to the left denoting the letter I, and to the right the letter V, this instrument obtained the name of 'I and V Telegraph.'

In the autumn of the following year (1842) Mr. Bain patented his proposed plan for working an electric telegraph 'without any galvanic battery whatsoever,' or, more correctly speaking, with a peculiar form of battery. At one end of the line he buried in moist earth a large plate of zinc, and at the other end a plate of copper, iron, or other substance such as coke or charcoal, which might set the part of a negative plate to the zinc. Then on connecting these distant plates with a wire insulated from the earth, a current of electricity would constantly pass from one plate to the other. Indeed the very idea that such a current should be connected with the earth, as above described, may be regarded merely as a battery of one pair of plates, separated by a very wide interval of exciting material, resting on earth. It was at first supposed by Mr. Bain that this current would be sufficient for its conveying purposes, but subsequent experiments showed that it was available only for a few miles of distance; its intensity being insufficient to travel through any great length of wire. In some cases, where a large current of a uniform intensity is required, this earth battery would become very useful and important.

In the early part of the year 1843, Mr. Cooke specified his patent for what has been probably the most important part of the invention, regarded in a commercial point of view. This was in reference to the mode of extending the wires between distant places, so that their insulation from one another and from the earth, might be maintained without the heavy expense and unavoidable difficulty hitherto incurred. Before this period, the wires having been covered with cotton and insulated by coating them with shell-lac, resin, or pitch, had been laid down in tubes or pipes of wood or iron. This method had been adopted on the Blackwall line, in 1840, and has not since been altered. On the Great Western Railway it was superseded by the new and improved mode of insulation. Mr. Cooke now proposed to insulate the wires by suspending them in the air upon posts or standards of wood or iron; the wires not being in actual contact with any part of the earth or other conductor, the bar magnets being removed from the earthware. The standard were usually fixed at from forty to sixty yards, and at each quarter of a mile a stouter post was set to, to bear the winding or straining apparatus.

This was a simple winding-post, connected with a quadrant-wheel and click to prevent its recoil, after the wire had been strained up by its means. The intermediate posts within each quarter of a mile were simply supported on the ground without reference to its tension, which depended solely on the weight of wire. Instead of the copper wires hitherto employed, iron wires of a larger size were now used: By the adoption of this method of extending the wires, the expense of erecting a telegraph was reduced nearly one-half, and at the same time the risk of imperfect insulation was diminished. So long as the wires were buried in tubes beneath the ground, it was no better than if they had been stretched from one end of the line to the other; if it was found very difficult to render the insulation sufficiently good to enable the earth itself to be used as half of the circuit. The conductivity of the electric fluid to escape from the wires in the tubes, to the earth, was much greater than to another wire lying in the same position, so that the latter plan was always adopted. But when the suspenders conductors came into operation, the insulation was rendered so complete, that the earth was subsequently in all cases used to return the current, by which means an economy of one wire throughout the whole line was effected.

In addition to this, another very decided advantage was gained by the suspension of the wires, in the facility of which accidental errors or injuries were discovered and rectified. While the tubes were in use, it was necessary to supply at about each quarter of a mile along the line, a proving or testing post, where the instrument was connected to the main line to afford the means of examining any of them as to their insulation and conducting power. For this purpose Mr. Cooke had invented an instrument called the Detector, by which the presence or absence of any error or fault discovered with considerable accuracy. Bell with all these appliances, the detection and repair of any derangement of the wires demanded considerable skill, and led to no small expense. But when the wires were in sight throughout, any contact or fracture was at once visible, and was easily and quickly repaired.

Having traced the invention through a few of its most remarkable stages, up to the time when it assumed the form it presented in England, we may add a few words on the method of applying it to the purposes of a railway. Mr. Cooke's first plan was one of admirable completeness in all its details. We can do little more than indicate its outline, as the full description would occupy far too much space. He proposed to divide the entire line of a railway, if necessary, into portions including each from four to six stations, and to make the traffic and communications within each of these divisions wholly independent of those on any other portion. The stations at which these partitions were to be termed Division Stations, and might be relatively, as above delineated, as above described, or any other form, the termini of each division, and the actual termini of the line, so as to bind the whole of the sub-divisions together in the most perfect manner, and yet maintain a considerable correspondence between the most distant points. Each station possessed a wire of its own, extending from one to the other termini of its division, and including at every station a pole or pillar, with a coil and a broad wire current of a uniform intensity, as before described, signals by any wire and system of needles, was provided at each point, so that the most ample means of correspondence was secured between all the stations. Each needle was used to denote the condition of that part of the line which was under the control of its own station; and by its means the movements of all trains upon this portion of the railway were made known to all the stations in the same division. As the signals made by any needle were simultaneously visible by the corresponding needle at all the stations, and as all information respecting the arrival or departure of trains, state of the line, accidental impediments, &c., was immediately indicated by known signals upon the telegraph, the station master at any point had only to turn to his instrument, to perceive at a glance the existence of any circumstance which might influence the working of the line at any station. Nothing was left to
be issued or inferred, was evident and visible, and in fact, in the words of Mr. Cooke, the clerk at each station possessed in his telegraph a constant bird's-eye-view of the whole of his division.

In addition to these 'line' wires, as they may be termed, there were in every case facilities extended throughout the line, with instruments at each station, so as to afford the means of verbal communication, whenever this might be necessary. The result of such a complete system could hardly fail to be most beneficial, and experience has now proved how accurately and justly all Mr. Cooke's measures were planned beforehand.

The Blackwall line absolutely depends upon this instantaneous means of communication, not only for its safety, but for the very possibility of its being worked. On this railway however the telegraphic system is different, insomuch as from its peculiar locomotive plan, the stations do not require any communication between themselves, but only with the two terminal.

Even on railways possessing a double line of rails, so complete a arrangement as that described in reference to the Vernon and Norwich line, would tend much to the prevention of accidents and increased safety of travelling. To prove this it is hardly necessary to recall to mind the disasters which have occurred, and still do occur at times, from the want of intelligence as to the unexpected approach of a train, or its undue delay on a particular part of the journey. Where there does not exist however an absolute necessity for such a system, its unnecessary expense would be likely to deter its adoption. In order therefore to meet the requirements of the railway as economical a mode as possible, a modified system has been adopted. The same plan of divisions and of communication is still adhered to, but these lines-needles are dispensed with, and merely the ordinary telegram retained at the subordinate stations. Usually the instrument possessing two needles and requiring two wires, is preferred for both the general and the divisional telegraph, as experience has shown that it is, taking all things into account, far superior to any other. The single-needle instrument, with one wire, is sometimes used for the small stations; but where due to frequent occurrence of a considerable length, it has been found that it cannot be used with advantage, from the diminished rapidity of signalling, as compared with the double needle.

It is evident that in the system above described no subordinate station can communicate directly with another station beyond its own division. Intelligence therefore referring to a distinct portion of the line, would be sent in the first place to one or other of the terminal stations of the division, and from thence would be forwarded again as required.

In England, up to the present time, the electro-magnetic or 'electric' system (introduced on one or more occasions the needle-telegraphy, of Professor Wheatstone, has not been adopted; the needle-instrument, from the great rapidity with which messages can be sent, and from other causes, having obtained very generally the preference. It is now however rendered capable with particular systems of working a line of railway, and in some cases for the transmission of political or commercial intelligence, where accuracy is required. It is now in use in England, and has been entirely approved of. Within this last year or two a great and important improvement has been effected in the mechanical instrument, by the use of the electric current derived by induction from a permanent magnet, instead of the voltaic battery. This plan is not applicable to the needle instrument, but is peculiarly so to the electro-magnetic telegraphy; while at the same time a permanent and unalterable source of electric power is substituted for the galvanic battery. Although this system is now employed for telegraphic purposes is sufficiently constant in their action, yet this is a most important advantage, obviating as it does all necessity for change or renewal of the source of electrical power.

Referring to our readers incidentally to the extent to which the electric telegraph has been adopted in England, at the present time. We therefore subjoin the following statement of the lines of telegraph in actual operation:

| South-Western | 99 |
| South-Eastern | 88 |
| Romney branch | 30 |
| Maidstone | 10 |
| Tunbridge Wells, &c. | 12 |
| Blackwall | 5 |
| Eastern Counties: Colchester line | 81 |
| Thames junction | 3 |
| Cambridge line | 88 |
| Herford branch | 7 |
| Ely and Peterboro' | 26 |
| Norfolk Railway | 38 |
| Yarmouth and Norwich | 20 |
| Lowestoft branch | 10 |
| Wolverton and Peterboro' | 57 |
| Eastern Union | 17 |
| Midland Counties: South line | 49 |
| West line | 41 |
| North line | 78 |
| Derby and Lincoln | 41 |
| Sheffield branch | 5 |
| York and North Midland | 23 |
| Hull and Selby and Milford Extension | 40 |
| York and Scarborough | 48 |
| Great North of England: York and Darlington | 45 |
| Richmond branch | 9 |
| Newcastle and Darlington | 39 |
| Durham branch | 2 |
| Sunderland | 6 |
| Shields | 3 |
| Preston and Wyre | 20 |
| Great Western | 19 |
| South Devon | 29 |

Total 1041

This list does not include several lines on which the telegraph is yet only in partial operation or now being erected. Among such may be specified the Leeds and Bradford, Leeds and Manchester, St. John and Peterboro', Newcastle and Berwick, North British, Hull and Bridlington, &c.

TELEGRAPHIC. TEMPLE. TEMPEL. TEMPLE. TEMPLE. TEMPEL. TEMPEL

TEMPLE. TEMPLE. TEMPLE. TEMPLE. TEMPEL. TEMPEL

This paper is somewhat of the subject of the Wellington exhibition, and it is therefore natural that the English telegraph should command our attention. The disastrous effect of accidents arising from trains meeting or overtaking each other, although it is a subject of great importance, is not, however, an exclusive property of electric telegraph lines; accidents constantly arise from the same cause, and it is necessary to adopt some system of telegraphic communication to check their occurrence.

The system now adopted in England is a simple one, and is based on the principle of the electric telegraph. Each station is provided with an electric battery, which is connected to the next station by a wire, and is thus able to send and receive messages instantaneously. The battery is capable of sustaining an electric current for a considerable length of time, and is therefore able to transmit messages over a considerable distance without the necessity of frequent renewal. The messages are transmitted in the form of dots and dashes, which are produced by a key, and are received by a similar key at the other end. The dots and dashes are transmitted at a rate of four words per minute, and are read by a telegraphist who is stationed at each station.

The system is simple and easy to understand, and is capable of being operated by a small number of persons. It is also cheap, and requires little maintenance. The cost of the apparatus is about £50 per mile, and the cost of maintenance is about £2 per mile per annum. The telegraph is operated by the Government, and is used for the transmission of important messages, such as orders for the military and civil authorities, and for the communication between the different parts of the country.

The telegraph is also used for the transmission of news, and is therefore very useful for the purpose of communication between different parts of the country. The telegraph is a great convenience, and is becoming more and more extensively used. It is a great improvement on the old system of communication by horse and mail, and is therefore to be highly commended.
Vendore and Purchaser, P. C. With respect to the provisions of this Act all must admit that they are beneficial. The principle that by a sublety a subsequent purchaser might obtain a priority over the bond file, purchaser was unjust and would only have been resorted to by judges if the legislature had not left the laws of property in an incomplete state. This devise of assignments of outstanding legal interests was but a clumsy and imperfect substitute for a general act with this addition, that it protected one innocent purchaser at the expense of another. There are, in opinion of many, some technical objections to the statute, which we cannot here enter into; but its evil will be removed. TERRITORIES OF INDIA. The information which was promised, in the article BENGAL, P. C., p. 232, to be given under the head BARTISH INDIA, is given under that of EAST INDIA COMPANY, P. C. The area of Hindustan, from the Brahmaputra to the Indus and from the Himalaya Mountains to Cape Comorin, has been estimated at about 1,200,000 square miles, and the population at about 120,000,000. The British possessions from the Ganges eastward to the frontiers of Birma will be included, the entire area may be estimated at 1,270,000 square miles, and the entire population at 140,000,000.

The following tables are given, in the deficiency of official returns, merely as approximations, in order to afford such a general view as may be useful, though not accurate, of the areas, population, and possessors of the territories of Hindustan:—

1,270,000 140,000,000
The Bengal Presidency comprises the provinces of Bengal, Bahar, Benares, Allahabad, Orama, Cuttack, Gudwana, the Ceded Districts on the Nerbudda, and the British territory east of the Ganges to the frontiers of British India. The North-West Provinces comprise the territory of the late Agra Presidency, which was established by an Act, 3 & 4 Wm. IV. c. 85 (August, 1823), but suspended by a subsequent Act, 6 & 7 Wm. IV. c. 154 (August, 1828), which empowered the Governor-General to appoint a lieutenant-governor of the North-West Provinces, and also from time to time to declare and limit the extent of the territory placed under his administration, and which was limited by the Act of 1828 before his death a powerful army and large stores of arms and ammunition. He was succeeded by his son, who having since died, and the present Maharaja, Dhuleep Singh, who succeeded him and is living very young, is being very unjustly kept in confinement by his father's courtiers. The Madras Presidency comprises the Northern Circars, the whole of the Carnatic, and extends westward across the peninsula as far as the province of the Madura (Madalar, Canara, &c.) south and west of Mysoore.

The Bombay Presidency comprises all the British territory on the west side of Hindostan from Canara northward, the Coromandel South Maharta country, Goacon, Candia, Coromandel, Surat, &c. The Bombay Presidency will probably be made to include Sind, which was annexed to the British territory in March, 1843, and is yet (1845) under a separate governor. The province of Bahar, under Sir J.T. Basset, was added to the British territory a portion of the Lahore territory on the east banks of the Ganges and Sutlej, and the Jullundur Doab, between the Beas and the Sutlej, with a considerable portion of hill-country which extends north-east towards the upper Provinces of India. By the treaty of peace with the Maharajah of Lahore, the British assume the control, in respect to tolls and ferries, of the Beas and Sutlej, the Ganges, and the Jallunder, and the control of the Indus from Mithakote to the borders of Beloochistan.

Each Presidency is divided into Collectorates for purposes of revenue and administration, but accounts are not published of the extent and amount of the Collectories separately. A general statement of revenue is published for each Presidency. The last actual statement (not an estimate) is for the year 1843-4, as follows:

- Bengal Presidency: £7,928,500
- North-West Presidency: £4,195,438
- Madras Presidency: £3,601,966
- Bengal Presidency: £2,046,728

Total receipts from assets in England and China: £1,131

Total Income: £17,173,788

Total charges in India: £15,668,843
Total charges in England and China: £2,944,073

Deficiency: £1,842,918

The total amount of the public debts of the Presidencies, on the 30th of April, 1844, was £3,539,830, bearing annual interest amounting to £1,761,622.

British India, strictly speaking, comprises only the territory which is actually in the possession of the British government, but the whole of Hindustan from the Indus to the frontiers of Birma, where the exception of Nepal and Bootan, is under British suzerainty and control, and in fact forms one great body politic, of which the British government is the head. The late Nawab of Gherat, Sir Haydn, was, in the opinion of some, feodatory, and some are restricted, according to the circumstances and treaties under which they became dependent. The new Cashmer state is feodatory. Glodiah Sing is the new Nawab of Lahore, government annually one horse, twelve perfect shawl-goats (six male and six female), and three pairs of Cashmere shawls, as an acknowledgment of the supremacy of the British government. The government of Lahore is limited by the new treaty to 25 battalions of infantry, consisting of 800 bounties each, and 12,000 cavalry. If a larger army should be necessary in any emergency, it may be increased by detachments from the army of the British government under the limits of the Lahore territory are not to be changed without a serious concurrence. All the dependent states are prohibited from making treaties of alliance with each other. The Portuguese still possess Goa, with a small territory around it, and the port of Damman; the French, Pondicherry, Madag, and Corisville. Scarampore and Tranquebar have been recently purchased by the British government from the Danes.

The circumstances of the annexation of Sind to the British territory are stated in the article Sind, F.C.S.

The late ruler of the Panjab, Ranjeet Singh, always remained on terms of amity with the British government in India, and the late Maharajah, Dhuleep Singh, who succeeded him and is living very young, is being very unjustly kept in confinement by his father's courtiers. The Sikhs army however mutinied and unprovoked, and the result was that the Lahore government, in order to extract themselves from the dangers to which they were constantly exposed, the city of Delhi, and having very recently secreted its garrison to the leaders of the Sikhs troops in making an attack on the British frontier. The Sikhs army began to cross the Sutlej, Dec. 11, 1845, and, after investing Ferozepore on one side, took up an intrenched position at the village of Ferozeshah, about ten miles in advance of Ferozepore, and about the same distance from the village of Moodkee. In this camp the Sikhs had placed 105 pieces of cannon, and a force of upwards of 50,000 men, in order to intercept the British force which was advancing from Umballah to the relief of Ferozepore, which had been attacked without provocation or declaration of hostilities. The British Army, under Sir Hugh Gough, commanders-in-chief, entered the rapid march of 150 miles, reached Moodkee, Dec. 18, and on the evening of the same day required an attack of the Sikhs army and captured 17 guns. On the following day the army was continued, a small body moved towards Ferozepore; and having on the march formed a junction with Major-General Sir John Liddler, who had with him 5000 men and 21 guns, Sir Hugh Gough formed the army in order to attack the main Sikhs' intrenched camp, and on the evening of Dec. 22 captured 74 pieces of cannon, took possession of the camp, with large quantities of ammunition and warlike stores, and compelled the enemy to retreat to the west side of the Sutlej. The British force on this occasion consisted of 16,700 men, and 66 guns, chiefly horse artillery.

The Sikhs forces were variously estimated at from 40,000 to 60,000 men, with 108 pieces of cannon of large calibres and in fixed batteries. Sir Henry Hardinge, governor-general of India, was engaged in this battle as second in command. The total killed of the British was 604, the total wounded 172; in all 2415. The British took 91 pieces of cannon. The loss of the Sikhs must have been very large.

Major-General Sir Harry Smith having with much difficulty and loss of some men brought a junction with the troops at Loodiana, who, hemmed in by a formidable body of the enemy's troops, the Sikhs army then retreated, and took up an intrenched position at Budawl, from which they were also compelled to retreat down the Sutlej by Sir Hugh Gough, having been reinforced by about 40,000 regular troops, 12 pieces of artillery, and a large force of cavalry, from the right bank, they advanced towards the British forces in order to intercept their communication with the main army, intrenching themselves near the village of Allival. The Sikh camp was carried by storm on the 28th of January, 1846, the whole of the enemy's cannon and munitions of war captured, and his army driven headlong across the Sutlej by a difficult ford. Fifty-six guns were taken by the British, and 11 others were sunk in the river. The total of British killed was 151, the total wounded 413, total missing 25; in all 589. The commander at the battle of Allival was Sir Harry Smith.

The result of this second victory was the evacuation by the Sikhs garrisons of all the forts previously occupied by detachments of Lahore soldiers on the left bank of the Sutlej, and the submission of the whole of the territory on that side of the river to the British government.

Meantime the main body of the Sikh army had taken a position on the left bank of the Sutlej near Sobran, and formed a strong bridge of boats, and a strong battery on the left bank, which Sir Hugh Gough did not deem prudent to attack till the Siege of Sobraon was continued by Sir John Liddell, which continued to the end of the year 1845. In the beginning of 1846, having arrived on the right bank of the Sutlej, the British army was intrenched on the same day, which had been reinforced by Sir Harry Smith with the victorious army of Allival, the attack on the Sikhs made on the 10th of February. The enemy's camp, strongly intrenched, defended by 35,000 men, and 67
pieces of artillery of large calibre, with a considerable camp and some artillery on the opposite bank of the river, was strengthened by a battery under Sir Hugh Gough, and after two hours of desperate resistance on the part of the Sikhs, they were driven into and across the river with immense loss, 67 guns having been captured by the British. Sir Hugh Gough, according to the effects of the fall, was also in this battle. The loss of the enemy is sup-
prompted to have been from 8000 to 10,000 men. The loss of the British was 230 killed, 2035 wounded; in all 2355.

The fall of the Sikhs and their retreat from the west bank of the river, having been defeated in every action, with the loss of a vast number of men and 320 pieces of field artillery. The British army crossed the Satleuj, engaged the Gurmukh and the Maharaaj Bhuleep Sing, his heirs and successors, on the other, was concluded at Lahore, March 9, 1845. A similar treaty was concluded with the Maharaja Gholab Sing at Umbrit, or Amrit, March 16, 1845.

Sir Henry Hardinge has since been created Viscount Hardinge, with an annuity of 3000L, and Sir Hugh Gough has been created Lord Gough, with an annuity of 3000L, to the two surviving heirs male of the body of each by whom the other two receive the respective titles; but the Court of Directors of the East India Company having granted to Sir Henry Hardinge an annuity of 3000L, and to Lord Gough an annuity of 4000L, particular of the official provisions of the East India Company, etc. it was enacted that the government annuity of 3000L should not be paid to Viscount Hardinge till after the annuity of 3000L granted to Lord Gough, and an annuity in like manner was granted by the East India Company to Sir Hugh Gough, it was enacted that only one-half of the govern-
ment annuity should be paid to Lord Gough till after the East India Company's annuity terminates. The two annuities granted by the East India Company commence from the date when the British troops arrived at Lahore. Viscount Hardinge has therefore 4000L a-year, and Lord Gough 3000L a-year. Their two next surviving heirs male of the body of each will have respectively the government annuities of 3000L and 2000L.

(Tamils, P. C.)

TERTIUSIANUS, Jurist. [Tasteullianus, P. C.]

TERRA ESTEN, AUGUSTYN, was born at the Hague in 1649. He became at about twenty years of age the pupil of N. Wieling and W. Doudens; before this time he had maintained himself by working and chasing for goldsmiths. In 1673 he went to Italy, where he studied chiefly in Venice and Rome, and visited France and England; and after an absence of six years returned in 1678 to the Hague, where he continued to be employed by his historical and mythological compositions, sacred and profane, but his favourite author was Ovid. He restored the Academy of the Hague, which had declined to a very inefficient state; and in 1696 he was invited by Emperor Leopold I. to the courts of Prussia, Prussia, and Berlin, and was appointed his court painter. He contributed chiefly to the establishment of the Academy of Berlin, of which he was made director. He died at Berlin in 1711. He presented with remarkable rapidity and freedom; there are a few etchings by him.

(Hoobraken, Grosse Schouwburg der Konst Schluders, etc.)

TESSELATED PAVEMENTS. [Tiles and Pav-
ements. P. C. S.]

TEST ACT. [Boroughs, &c., P. C., p. 209.]

TESTE DE A WRIT. [Writ, P. C.]

TESTELEIN or TETTELEIN, LOUIE, was born at Paris in 1616, and was a pupil of Voset. He was elected one of the original members of the French Academy, though he was only thirty-three years of age at its establishment in 1635. His presentation picture was an historical portrait of Louis XIV. In 1650 he was appointed one of the professors of the academy. Testelin's picture of the Resurrection of Tabitha by St. Paul, painted in 1652, is considered one of the masterpieces of the French school of painting, and is com-
pared with Le Sueur's celebrated picture of Paul Preaching, and the Burning of the Books at Ephesus; it is in the church of Notre Dame; there is a print of it by Rocque and Picard de Rancourt, and the Maharaaj Bhuleep Sing in the church of Notre Dame— the Flagellation of St. Paul and Silas, which was painted in 1655, the year of his death.

St. Louis attending a sick man, in the Hospital de la Charité, is likewise a distinguished work by Testelin. As he died at the early age of forty, his works are necessarily scarce. A few among the whole night through, Le Brun rose, saying, 'My friend, you have charmed me by your profound knowledge; the victory is yours; certainly no man is better instructed in the great mystery of this art.'

(D'Argenville, Abrégé de la Vie des Peintres, &c.)

TETRAGONOLEPIS, a remarkable and numerous genus of fossil ganoid fishes, chiefly from the limestone strata of Dorset-
shire. [See Argentine, &c.]

TETRAN' Theria, a genus of plants belonging to the natural order Laureceae. The flowers are discoid, some hermaphrodite, inovulculated. The calyx 6-parted, the seg-
ments nearly equal or wanting. The fertile stamens generally about 9, in the petalsoid flower from 12 to 21. The leaves are variable, with pinnate veins.

T. K., a large spring in the valley, a native of the mountains of India and China. The leaves are ovate, oblong, acute at the base, smooth and shining above, more or less downy beneath. The umbels rather compound and nearly white. The fruit is a case, yellow or brown, containing a pea, yielding a kind of greasy exudation from which the Chinese prepare preservative candles of a bad quality, and which serves as a basis for salves. This fixed oil is supposed to constitute the principal part of the fruit of Persicaria protistina, so much esteemed in the West Indies under the name of Avocado Pear.

(Lindley, Vegetable Kingdom; Lindley, Flora Medica.)

TETRAPODON, [Gymnobranchia, P. C. S.]

TETRAPHERUS, a genus of fossil fishes from the Cre-
aceous and Tertiary strata. [Agracn.]

TEXAS. This country lately formed a portion of the territory of Mexico. The revolution through which it became separated, arose from the permission given to immi-
grants from the United States to receive grants of lands. The first permission of this kind was conceded to Moses Austin in January, 1821, which on his death was extended to his son, Stephen Austin, and confirmed by the Mexican Cortes, April 14, 1823. These and other similar concessions were made on condition of bringing into the country from 500 to 200 families as the consideration of each grant of land.

Texas formed part of the State of Coahuila in the confed-
eration of the Mexican States. It was established as a state August 15, 1824, and the State Constitution was pro-
mulgated in March, 1827.

In 1829 there was a convention between the Mexican troops and the American settlers occurred. This was followed by various conflicts and at last the independence of the country was proposed, when Stephen Austin adviced that no limits of territory should be fixed, and the means of defense to Texas should be left open to extend beyond the Rio Grande to Chihuahua and New Mexico.

On the 21st of April, 1836, the battle of San Jacinto was fought between the Mexican and Texan forces, when the president of Mexico, General Santa Anna, was taken pris-
ero by General Houston. This event terminated all Mexican authority in the country.

In 1837 the Committee of the United States was formed to attend the House, that the independence of Texas ought to be recognized, and was continued upon the table—but at the last hour of that session of Congress, by the President of the United States, an amendment to the General Appropriation Bill was carried, for the payment of the outlay of government of Texas. This amendment which the President should receive satisfactory evidence that Texas was a independent power. Immediately after this bill was
signed by the President, the nomination of a Chargé d'Affaires of Texas was sent by him to the Senate and consented to by it—and thus it was, that the Republic of Texas was recognised by the United States. To have effected this recognition by treaty, a majority of two-thirds, inclusive, and such a majority could not then have been obtained. A mere majority was sufficient to confirm the nomination of a Chargé d'Affaires.

On September 25, 1839, a treaty was signed between France and Texas, and was ratified at Austin, Jan. 18, 1840. This was the first recognition of the independence of Texas by a European power. On Nov. 16, 1840, a treaty between Great Britain and Texas was signed, and was ratified at Austin in Feb. 1841. But no treaty was made between the governments of the United States and Texas; and in consequence of no such treaty being required as a condition precedent to the recognition of Texas independent by this country, the annexation of Texas to the United States was greatly facilitated.

The government of Mexico persisting in its refusal to acknowledge the independence of the country, proposals were made to annex the Republic to the United States. The trade and security of the people settled in the western district were constantly disturbed—marauding incursions were common, and the government had not pecuniary resources sufficient to enable it effectively to carry on a war. It had been hoped that the influence of France or of Great Britain would have checked the evils arising from the obstinacy and weakness of the Mexican authorities. Nothing happened that did not happen, public opinion became favourable to a union with the United States, and this feeling was further stimulated by the efforts of Presidents Tyler and Polk, both of whom strongly urged upon the Congress of the United States the policy of taking advantage of the opportunities afforded by the political condition of Texas. On the passing of an Act by the Texas Congress to surrender its independence, in December, 1845, an Act of Congress of the United States declared Texas to be one of the States of the North American Union. The boundary between Texas and the United States was fixed by the Florida Treaty of 1819. The Congress of Texas declared the western limits of Texas to extend to the Rio Grande, including the department of New Mexico, which had never formed part of the State of Texas or Colombia, and was settled by the Spanish as early as 1690.

The government of the United States, since the annexation of Texas, appears to make a claim to the same extent of territory, and there is also every probability that one of the results of the pending war with Mexico will be to extend the authority of the United States over the entire province of California.

Address of J. Q. Adams to the Electors of Braintree, September 12, 1842; Kennedy's Texas; Congressional Documents of the Senate of the United States, 1846; Falconer on the Discovery of the Mississippi, 1844.

THAW is the reduction of ice or snow to a liquid state in consequence of an increase of temperature. This effect is produced on the surface of the earth or in the atmosphere during the spring season by the return of the sun to the hemisphere of the observer, the solar rays then falling in greater abundance than before on a given extent of ground; or it is produced by accidental currents of warm air which pass over a frozen mass. The dissolution of the particles of ice in the atmosphere is the cause of the humidity which accompanies a thaw.

As the conversion of a liquid into ice always commences at the surface of the former, and about the sides of the vessel containing it, or about those of a solid body immersed in it, so in ice surrounded by air which has acquired a higher temperature than the ice has, the process of liquefaction commences at the sides and extends gradually from thence inwards; ice being a bad conductor of heat, the central parts of it are the last which are dissolved. It is observed that when solid bodies, whose temperatures are equal to one another and higher than that of ice, are applied to the latter, the ice is dissolved most rapidly by those which have the greatest power of conducting charcoal; thus a piece of ice being laid on a plate of polished metal, and a piece of equal magnitude on wood, the ice on the metal will be dissolved before that which is laid on the wood, not only when the temperature of the metal and wood are equal, but even when the temperature of the wood considerably exceeds that of the metal, the latter conveying more abundantly to the ice the calorics which it is continually receiving from the charcoal.

A severe and long-continued frost abstracts so much calorics from terrestrial bodies, as the walls of buildings which are not exposed to the sun, that these are often cooled below the temperature of freezing water; and while in this state, if a current of warm air pass over their surfaces, the water which the air holds in solution deposits itself on the walls, where it is converted into ice or snow; it remains thus frozen for a time after a thaw has commenced, but at length, the temperature increasing, the ice is melted and the walls are then covered with moisture.

It is often remarked that at the time of a thaw taking place there is felt a degree of coldness greater than that which is experienced during the continuance of the frost; this is apparently caused merely by the evaporation of the moisture which is then on the skin, for the thermometer at the same time indicates an elevation of temperature in the atmosphere.

The overflowing of rivers by the dissolution of the snow and ice on the mountains about their sources is well known, and to the liquefaction of the ice formed by the previous congelation of water which has introduced itself in the fissures of rocks is to be ascribed the occasional servitude of large masses from the sides of mountains; the expansion of the water in freezing having destroyed the cohesion, so that the parts are only held together by the ice, and on the liquefaction of this the disunion is complete.

Thebes. The writer of the article THEBES, P. C., has, owing to a misapprehension, given references to Carnac and Luxor, instead of describing them under the article Thebes.

We now supply the omission.

On the site and amongst the ruins of the ancient city of Thebes stand four principal villages, Carnac and Luxor on the eastern bank of the Nile, Gournou and Medinet-Abou on the western bank. At Luxor, near the river, are the remains of a temple, the entrance to which is through a magnificent propyleon, or gateway, consisting of two pyramidal piles, the lower part of which is now concealed by accumulated sand, but which probably form a propylon as large as that of Carnac hereafter described. In front of the propylon, which is covered with elaborate sculptures, stood two of the most perfect obelisks known to exist, one about 82 feet high, the other 76, and from eight to ten feet wide at the base. The

[Vol. II.—4 L]
smaller obelisk has been removed by the French, and now stands in the Place de la Concorde at Paris. A ship constructed expressly for the purpose of transporting the obelisk sailed from Constantinople to Alexandria in 1831. The obelisk was selected as not only lighter, but in a better state of preservation than the larger. This obelisk was found to be placed on a higher pedestal than the other, and somewhat modified in form to make the difference of size less apparent to the spectator. The obelisk was lowered, conveyed to Paris, and erected Oct. 25, 1836. The cut on the preceding page presents a view of the two obelisks with the propylaeum and them, and a portion of the ruins of the interior of the temple.

But the remains of Carnac, about a mile and a quarter lower down the river, are still more wonderful than those of Luxor. An irregular avenue of sphinxes, 380 yards in length, connects the southern entrance of Carnac with the northern entrance of the temple of Luxor. Carnac is about 830 yards from the east bank of the Nile, and is surrounded by a wall of unfinished bricks about 800 yards in circuit, or more than three miles. An adequate idea of the extent of the remains in this inclosure could only be given by a plan on a large scale. The largest of them, some have thought to be a temple and some a palace; (it may have been both) is 159 feet in length, 360 feet in its greatest width, and 392 feet in its least width. The entrance to it (the western entrance) fronts the Nile, with which it is connected by an alley of carioles, formed of a lion and a head of a ram. This alley consists of a propylaeum, without sculpture, 360 feet long and 148 feet high, with a great doorway in the centre 64 feet high; passing through which a large colonnade, 44 feet high, with a range of pillars to the west, and a double row of lofty pillars down the middle, which terminate opposite two colossal statues in front of a second propylaeum. A flight of twenty-seven steps then leads to an entrance hall, which has been called the Great Hall or postyle Hall of Carnac. It is 388 feet by 170 feet, and comprises an area of 67,629 square feet. The roof, which is flat, and when perfect was formed of very large slabs of stone, is covered with a roof of brickwork. The roof is eleven feet in diameter and the smallest nearly nine feet. Four churches of the size of that of St. Martin's in the Fields, London, might stand side by side in this vast hall without occupying the whole space. The interior propylaeum, pillars, and walls are covered with sculptures. Four beautiful obelisks form the entrance from the hall to the apodyton, or sacred place, which consists of three apartments, all of granite, and the central room, or sanctuary, is adorned with sculptures, and painting and gilding. Beyond the apodyton are porticoes and galleries, which were probably continued to another propylaeum.

Four propylaeum form the entrance on the south side, at the end of the long avenue of sphinxes leading from Luxor; and there was probably a similar one on the north side.

As an architect he designed the Casa del Ayuntamiento or mansion-house, of Toledo, and the churches of La Caridad and of the convent of the bare-footed Franciscans at Illescas; and he built the earlier obelisks and the smaller obelisk at the principal altar-piece of their college. He also designed the churches of the paintings and sculptures of these churches. In 1590 he designed the church of the Augustinians at Madrid, called de Donna Maria de Aragon, and painted the principal altar-piece of their college. He then designed the principal church of the Jesuits in Madrid, which are among his last works. He died at Toledo in 1625, according to Palomino, seventy-seven years of age; and was buried with great pomp in the church of St. Bartholomew.

El Greco's pictures were still very numerous at the end of the last century; Cean Bermúdez enumerates a great many in Toledo, Illescas, Escalon, Bayona, in Segovia, La Guarda, Mostoles, Casarrubios, Siguenza, Medina Celli, Valencia, Leon, at the Escorial, and in Madrid. Many have since been removed. Mr. Ford, in his 'Handbook of Spain,' notices only three pictures by this painter—Christ bearing his Cross, and a Nativity, and an Adoration, in the Salón de la Sagrada at Toledo.

Richard Cumberland speaks in high terms of the pictures of El Greco, especially the Preparation for the Crucifixion and the Parting of Christ's Raiment in the cathedral of Toledo, already mentioned, and the entombment of Don Gonzalez Ruiz, Count Orgaz, in the church of Santo Tomé at Toledo, which he considers his masterpieces. The first he terms a grand composition so entirely in the style and manner of Titian it must have been the work of Titian himself. The latter was painted for a family of the name of Orgaz, by the Augustin convent of San Esteban at Toledo, and this picture was painted in honour of the foundation—the saints Augustine and Stephen are represented depositing the cost in his tomb, and the picture contains the portraits of many distinguished persons of the time.

His son, George Samuel Theotocopolis, was also a sculptor and architect of eminence. He was appointed sculptor and architect to the king and the cardinal of Haro; and died at Toledo in 1631. He was the architect of the ocaqav of the cathedral: it is an octagon decorated with precious marbles and a painted dome, and is used as the treasury-house of the Virgin, where her splendid dresses are kept, as well as many precious relics.

( Cean Bermúdez, Diccionario Historico, &c.; Cumberland, Anecdotes of Eminent Painters in Spain.)

THE ELOIDUS, a fossil sauk from the upper Silurian strata of Ludlow. (Murchison.)

THEONOA, a genus of fossil Zephyrida from the secondary and tertiary strata. (Lamarron.)

THIBAUT, ANTON JUSTUS FRIEDRICH, a celebrated German jurist, was born on the 4th of January, 1772, at Hameln in Hanover. In 1792 he went to Göttingen to study law; he continued his studies at Königsberg; and he finished them at Berlin, where he entered the bar, and became a judge. In this university he took the degree of D.C.L., and in 1796 was admitted as a junior teacher of the law. He soon rose to eminence, and at the age of twenty-seven was appointed ordinary professor of civil law. In 1802 he went in the same capacity to Jena, where he published his 'System des Pandekten-Recht,' the first systematical attempt of the kind that was written in the German language, the former works on that subject having been written in Latin. The merits of this excellent work were generally acknowledged, and Thibaut was chosen by the Emperor Alexander one of the members of the foreign commission for the establishment of legislation for Russia, and in 1805 he was invited to the university of Heidelberg, where he remained till his death. Though scarcely thirty, he was considered to be the first civilian in the German Empire. He had not yet attained his great reputation. Twice Thibaut was chosen proctor of the university of Heidelberg, and nine times he filled the office of dean of the faculty. He was also chosen deputy of the university in the Prussian diets, but as his new duties interfered with those of a teacher, he resigned the office. In 1816 he was made a privy councillor. His fame and his popularity among the students led to his receiving the degree of doctor in Ellwagen, and in 1820 at Leipzig, where the place of professor of jurisprudence of law was offered to him with a very large income, besides a prebend in the chapter of Merseburg: but nothing could induce him to leave Heidelberg. In 1830 he was knighted by the Grand-Duke of Baden.
his former pupil, who in 1834 appointed him judge for the grand-duchy, in the newly established tribunal of arbiters for the Grand Duchy of Baden, and then (1837) for the court of civil and superior to a him as a teacher and a practical jurist. The great object of Thibaut was to distinguish clearly between the obsolete portions of the Roman law, and those which were of real value. In this he was much more amiable; to many a poor student he proved a kind father; to many who had talent, a wise friend. His house was open to all his pupils, whether introduced to him by others or by themselves. And particular attention was paid to students besides their legal knowledge, showed proficiency in music, of which he was a profound judge. His little work on Purity of Music quoted below is a specimen of his refined taste in this art.

The principal work of Thibaut is his 'System des Pandekten-Rechts,' mentioned above, of which the eighth edition was published at Heidelberg in 1834, 2 vols. 8vo., and a ninth edition in five volumes, by Professor Buchholz, Jena, 1846. This work is in the hands of nine out of ten lawyers in Germany, but though of the highest value, it is rather a difficult book to beginners. The following are the other works of Thibaut according to the date of their publication: "De Marriage," 1825, 4to.; "De Novamento," 1832, 4to.; "De Hochzeitsvertrag," 1826, 8vo.; "On Possession and Prescription," Jena, 1802, 8vo.; a work which caused a great sensation, but was afterwards thrown into the shade by Savigny's work on Possession. 3. "Civilische Verwaltungsrecht," Heidelberg, 1814, 8vo.; 2nd edit., 1822. 4. "Ueber Recht," Heidelberg, 1825, 8vo.; 2nd edit., 1820. 5. "Ueber die Nothwendigkeit einer Allgemeinen bürgerlichen Rechte in Deutschland," Heidelberg, 1814, 8vo. (On the Necessity of a Common Code of Laws for Germany.) This work placed its author at the head of a great legislative movement, and a short explanation is necessary in order that the reader may understand it. Anticipating German laws and a large portion of the Roman law exist there together, the former referring principally to landed property, entitled estates and others called 'noble estates,' the latter to the manors, and the manorial courts. The manor, the succession to such estates, the legal consequences of marriage inasmuch as it effects complete commutation of property, personal and real, between husband and wife, further details relative to civil and insolvency; while on the whole, contracts, the common succession to personal property and to land, except entitled estates either noble or villain, testaments (in a great measure) and many other things are regulated by the Roman law. In some parts of Germany the German and Roman elements of the law are knitted together by modern legislation into a regular code, civil and criminal, as the Austrian code; the Prussian, which is in force in the greater portion of the kingdom of Prussia; the Bavarian criminal code; the work of Feuerbach, in Bavaria and Oldenburg. But the civil law in the latter two countries and nearly the whole of Germany, except Austria and Prussia, is that compound of Roman and German elements which has been mentioned above. Besides the 'Common Law,' by which is meant the Roman-German compound aforesaid, there is a variety of provincial and local laws, among which the laws of the cities of Magdeburg, Hamburg, and Lübeck deserve a particular attention, especially the law of Lübeck, since it is not only shaped into the form of a code, but is the common law of nearly all the towns of Northern Germany as well as those in the adjacent provinces of Austria and Prussia, of Denmark, of Sweden, of Russia, of Poland, of Lithuania, and of Estonia. To augment the difficulties, the French code became the common law in the Rhineland provinces and in the grand-duchy of Baden.

The purpose of the present paper is to show that the administration of the law in Germany is no easy matter; and that the difficulties increase in proportion to the extent of the jurisdiction of the different courts; and hence the strange, yet under such circumstances necessary fact, that the faculties of law in the various universities were, and are still, of such a nature; and that the state is one which used-to be brought which require more learning, especially historical learning, than is generally possessed by the members of the common courts of justice. Thibaut's proposal was for a common legislation; that the idea itself was good, but that there were so many scientific (rather theoretical) differences among the jurists dividing the most important points, that every attempt would prove abortive till matters had previously been settled scientifically. Savigny also could refer to an example, the Prussian code ('Landrecht'), which, though only an experiment upon a portion of the laws, is yet considered to be a failure; he avoided to speak of the Austrian code. At present the opinion of Thibaut has more adherents than that of Savigny; and since the latter's views depend merely upon an eventuality which cannot but take place in the future, or at least it may be, it is to be presumed that the period when Germany will enjoy a common code is not so very distant. Thibaut has entered into many details concerning that important question in several of his numerous essays, dissertations, and treatises in all branches of law; one of the most interesting is his 'De Marriage.' He was the founder of the 'Civilistisches Archiv' and the 'Heidelberger Jahrbücher.'

(Thibaut, in Heidelberger Jahrbücher, year 1840.)

THIN PLATES. [COLOURS OF PLATES, P. C. S.] We take this opportunity of correcting an accidental mistake in the article referred to. It is there stated (p. 596, col. 2) that 'the thickness of the rings is the most and least luminous of the rings: whereas they are proportional to the squares of the semi-diameters of the rings.' Thalasp (a species of small, compressed, a genus of plants belonging to the natural order Cruciferae, and the sub-order Angiospermeae. It has a roundish notched boat-shaped, oval capsules with a longitudinal wing; the seeds are numerous, the petals equal, the flowers white. T. arvensis, Penny-cress, has oblong toothed leaves and erect stems, an elongated fruit-bearing raceme, orbicular capsules with a longitudinal wing. It is native throughout Europe and in England. The flowers are small and white, and the whole plant when bruised has a somewhat alliaceous odour. T. perfoliatus has obcordate pappus, the solitary leaves oblong, the petal equal in length to the calyx. It is a native of Europe and is found in England on chalky soil. T. alpaster is found on limestone mountains pastures throughout Europe and England; the leaves are entire, the radical leaves pinnate and entire, the inflorescences ovate, stellate; the style and stigmas 2; the petals nearly as long as the calyx, the pod obcordate, from 8- to 12-seeded. The species of this genus are hardly worthy cultivation except in general collections or in botanical gardens. They succeed best in a light sandy soil.

(From Gardener's Dictionary; Babington, Manual of British Botany.)

THOBALDSEN, BERTEL (Albert), was born November 19, 1770, at Copenhagen. He was the son of Gottschalk Thorvaldsen, a carver in wood, and his wife Karen Grünland, the daughter of a priest of Jutland. Gotta-

chak was a native of Iceland, and was in very poor circum-
stances when his son Bertel was born. Bertel assisted his father in his work at a very early age, and when only fourteen years old he attended the free school of the Academy of Arts at Copenhagen, and made such progress in two years that he was enabled to improve his father's carvings; and himself undertook to execute the head-pieces of ships. At the age of seventeen he obtained the silver medal of the academy, for a bas-relief of Christ and the woman of Samaria, and in twenty-two years of age, the small gold medal for a sketch of Heliodorus driven from the temple. Two years later he obtained the principal gold medal of the academy, and with the privilege of traveling for three years abroad at the government expense. Before setting out, however, he devoted a year or two to preliminary general study, for scholarship was not one of his acquirements, and he had much
to road and much to learn. On the 20th of May, 1796, he set out for Italy in the Danish frigate Thetis, and he arrived at Naples in the end of January of the following year, in the packet-boat from Palermo. The Thetis cruised in the North Sea in October, but he did not return to Denmark, which according to his own account he would have done if he had found a Danish vessel about to leave the port at the time. However, in a little time he found courage to engage a place in the coast of a vetturino for Rome, where he arrived March 8, 1797.

Thorwaldsen brought letters of introduction to his distinguished countryman Zoega, who however did not give the young sculptor much encouragement, nor did he estimate his ability very high. When Zoega was once asked what he thought of him, three years after his arrival, he answered with a shake of the head, 'There is much to find fault with, little to praise with, and he was upon his way at the time.' This time Zoega was right, except in the last particular. Thorwaldsen was industrious, but fastidious, and often destroyed what had cost him much labour. This was the fate of a MADELAINE with the Golden Hairs, which he had modelled to take back with him to Copenhagen at the expiration of his term of three years allowed by the Academy. He however made a second attempt at the same figure, and this statue was difficult to engrave. Lorenzo Zoegas praised Thorwaldsen was about to return to Denmark; and Canova exclaimed, 'This work of the young Dane is a new and a grand style.' By the assistance of a Danish lady, Frederika Brun, who gave him the necessary funds, he was able to have the statue in song, it was cast in plaster, and Thorwaldsen prepared for his return home; but when on the point of starting and about to step into the vehicle of the vetturino, one of his companions, a Danish sculptor Hansen, who was at the height of his skill, observed that his passport was not in order, and he was obliged to put off his journey until the next day. Thorwaldsen determined to wait with him, the vetturino started without them, this delay was followed by another, and it eventually happened that Thorwaldsen did not return to his native country until 1819, after an absence of twenty-three years. The liberality of Thomas Hope was the immediate cause of Thorwaldsen's finally settling in Rome. The works of Canova upon the statue of Jason were repeated in the artistic circles of Rome, and echoed by the professional eirenici of the place. One of these, a Count Marcolini, in 1803, came to the statue of the young Dane and saw the statue which the great sculptor had praised. The English connoisseur stood long before the plaster figure, then inquired what Thorwaldsen required for a marble copy, and was answered, 'You shall have 800,' was the generous reply of the Englishman.

From this time the star of Thorwaldsen was in the ascendant; the statue was however not finished until many years afterwards, but many celebrated works were done in the meanwhile; as the bas-reliefs of Summer and Autumn, and the dance of the Muses on Helicon; Cupid and Psyche; and Venus with the apple. His fame spread far and wide, and Christian, the present king (then crown-prince) of Denmark, wrote his pressing invitation to return to Copenhagen, communicating at the same time the discovery of a white marble quarry in Norway. Thorwaldsen was eager to return, but his commission rendered it impossible; he could not leave the papal city.

During this busy time Thorwaldsen recreated himself in the summer seasons at Leghorn, in the beautiful villa of Baron Schnitger, the Swedish minister at Florence: he executed also some of his works here.

In 1812, when arrangements were being made for Napoleon's visit to Rome, the architect Stern, who superintended the preparations upon the prescribed order, was one of the commissions of the Assembly of St. Luke, and asked him if he could get ready a plaster frieze for one of the large apartments of the Quirinal Palace, in three months. Thorwaldsen accepted the commission, made a model a month later, and had the frieze completed in three months, and a plaster sketch of his celebrated bas-relief of the Triumph of Alexander was completed. The immediate subject was Alexander's triumphal entry into Babylon: the length of the frieze is 160 Roman palms, its height five palms: it has been twice executed in marble, with slight variations, and is engraved in a series of plates by S. Amsler, of Munich, after drawings by Overbeck and others.

In 1819, in a single day, two of his most popular works, the bas-reliefs of Night and Day; but he had done nothing whatever for weeks and months before. In July, 1819, he started in the company of two friends on his first visit to his native land, and he arrived at Copenhagen on the 3rd of October of the same year: his parents had died some years before. His fame was now so well established, that even through Italy and Germany his journey was a special event of interest. His samples were shown to the King, who had them lodged in the palace of Charlottenburg and entertained with public feasts. In about a year he left Copenhagen and returned to Rome through Berlin, Dresden, and Warsaw, where he sent several commissions, and made a bust of the Emperor Alexander.

He executed his principal works after his return to Rome, as Christ and the Twelve Apostles; the group of St. John in the Wilderness; and the monument to Copernicus, Pius VII., Maximilian of Bavaria, the Poiniakowski monument, and others. In 1823 he had a narrow escape of his life: a boy, the son of his landlady, connived to get hold of one of his pistols, which he had left about the house, and the boy ignorant of the danger, pointed it and discharged it at Thorwaldsen, but the ball, after grazing two of his fingers, lodged in his dress without doing him any further injury.

In 1825, he received the commission to design a monument for the Pope, and the Apostles,—the principal works for the cathedral or church of Our Lady at Copenhagen,—and other works for the palace of Christiania, on which Thorwaldsen had been many years engaged, and which he had completed. He then received the frigate Rota to carry them and their sculptor to Copenhagen. Thorwaldsen was received with enthusiasm by his countrymen; and he remained among them on this occasion about three years, and never went to his friend the Baron Stampé, where a studio was built for him; and he finished here some of his last works—the frieze of the Procesion to Golgotha, for the cathedral; the Entrance into Jerusalem; and the death of the Virgin, which were finished, with the busts of the poets Oehlenschläger and Holberg. In 1841, finding the climate disagree with him, he felt compelled to return to Italy, and he executed at this time his group of the Graces for the King of Württemberg. He returned however to Denmark and Nyborg in the following year, and executed other works, bas-reliefs, which are among his last productions—Christmas Joy in Heaven; and the Genius of Poetry, which he presented to his friend Oehlenschläger. He intended to return to Rome in the summer of 1844, but he died suddenly in the theatre of Copenhagen, on March 31, in that year, aged seventy-three: he died of disease of the lungs, and was laid in state in the palace, and buried with extraordinary ceremony beneath his own greatest productions in the cathedral church of Copenhagen.

Thorwaldsen's portrait by 'Yngve' was sent to Sir F. Chantrey's; he bequeathed all works of art in his possession, including casts of his own works, to the city of Copenhagen, to form a distinct museum, which was to bear his name, on the condition that the city furnished an appropriate building for their reception. This building was nearly completed before the death of Thorwaldsen; 60,000 Danish dollars were subscribed already in 1842, and the museum fast approaches its completion. Besides the numerous works of Thorwaldsen, which would alone constitute an imposing collection of its class, it contains many works of ancient and modern sculpture, numerous paintings by old and recent masters, casts, engravings, etchings, engravings, cameos, medallions, curiosities, engravings, prints of all descriptions, books on fine arts, and drawings. With the exception of 12,000 dollars to each of his grandchildren, and the life-interest of 40,000 dollars to Madame Posthumus, his daughter, to descend to her children, the whole of his personal estate is to be converted into capital, and to be added to the 25,000 dollars already presented for the purpose by Thorwaldsen, to the sum of 65,000 dollars; and to make a fund from the interest of this sum for the purchase of the works of Danish artists, for the encouragement of Danish art, and to add to the collections of the museum. His daughter, now a widow, resides in Rome.
government is under five trustees, two always to be pro-
ferors of the Academy, one a magistrate of Copenhagen, and
one a citizen, chosen from the merchants, and one known
as the trustee, and all questions are to be decided by a majority
of voices. The trustees themselves will supply all vacancies as
they occur. There are at present six, but the perpetual num-
ber shall not exceed eight.

Thorwaldsen is considered by his admirers the greatest of
modern sculptors, and many have not hesitated to place him
far above Canova, and to compare him with the antique.
This is however hardly the rank he will hold with posterity;
his style is uniform to monotony, though many individual
figures are bold, solid, and of beautiful proportions. His
beau-idéal appears to have been something between the An-
icine and the Renaissance, but he has a characteristic
style; but as his subjects are seldom heroic, he seldom
required more than a moderate expression of heroic vigour or
robust strength and activity: in this respect, and in execution
generally, he was much surpassed by Canova; but still more
so in the grace of the female form, in which Thorwaldsen cer-
tainly did not excel. His females are much too square in the
frame, the head and shoulders being generally heavy; and
in no instance do we find in his female figures, in full relief, that
beautiful undulation of line and development of form charac-
teristic of the female, which is displayed in the antique, in
the works of Canova, and in those of some other modern sculptors;
as, for instance, the Ariadne of Dannocker. Baso-
rilievo was a favourite style with Thorwaldsen, and a great
proportion of his works are executed in this style. Of this
class some of his minor works are the most expressive; but
the most interesting are his representations of the goddesses
of Delos and of CARTHUSIAC; which is the frieze of the cathedral
church of Copenhagen, immediately below the numerous
figures of the Greek and the Roman order Compositive
molding oblong in one row, with a few additional
molding at the base. The receptacle is punctured, the fruit beaked.
The papaya in two rows, the outer row sepalaceous deciduous, the
inner one longer, feathery and dilated at the base. The
marginal row of fruits is enclosed in the scales of the in-
volute.

T. hirta, the only British species, has lanceolate leaves,
sinuate dentate, hairless or hairy. The leaves are all radical,
sometimes nearly or quite entire, occasionally runcinate. It
is found chiefly in gravel soil.

T. umbellata, the other one 2-leaved, the inner about
30 mm. long, is characterized by its calyx; the outer
3-celled and 2-celled. The species are handsome climbing plants
with a fragrant odour.

T. fragrans has a climbing stem, with cordate acuminate
leaves somewhat angular at the base.

T. griffithii has large flowers with no inner calyx; the
leaves are angular cordate; the anthers bearded and spurred.

This and the former species are natives of the East Indies.

Lindley, Encyclopaedia of Plants.

THUYTES, a genus of fossil coniferous plants from the
oolite of Stonesfield, Colwycombe, Greystoke, and Selen-
hofen (Bromlani)

THYNUS, the subdivision of the genus SCOMBER
(Mackerel) to which the fish called the Tunny belongs. The
Tunies differ from the Mackerels in the position of their first
dorsal fins, which, instead of being separated from the second
by a wide interval, are prolonged close one to the other.
The first dorsal fin is rather shorter than the second, and
at the thorax they have a coryphe of larger scales, a character
which is wanting in the subgenus SCOMBER. The Tunny and Bonito
are the best known examples. The former has nine
spines and five membranous finlets above and below; the latter
has eight above and seven below.

The general form of the tunny resembles that of the
mackerel, but it is thicker in proportion to its length. The
back is black with a white line from the head to the
head are whitish; the belly is grey, with silver spots;
the fins variously coloured; the first dorsal, pectoral,
and ventral are dusky; the tail is rather paler; the second
dorsal and anal more or less flesh-coloured, and the spiny
finlets sulphur-yellow, edged with black. The tunny grows
to more than seven feet in length, and when of those
dimensions weighs more than four hundred and sixty pounds.

The following interesting account of the modes of fishing
the tunny in the Mediterranean is given by Mr. Yarrell in his
'Technology of British Fishes'.

In the months of May and June, when seeking a proper
situation near the shore upon which to deposit their
spawn, the adult fish rove along the coast in large shoals and
are known to be extremely timid, easily induced to take a new
and apparently open course to avoid any suspected danger.
It is believed that this is a result of the small peculiarity to carry
on some elevated spot, makes the signal that he sees the shoal
of tunnies approaching, and the direction in which it will
come, a great number of boats set off under command of a
chief, range themselves in a circle, and joining their nets form
an inclosure which alarms the fish, while the fishermen drawing
closer and closer, and adding fresh nets, still continue driving
the tunnies towards the shore. When they have reached the shallow water, a large
net is used, having a cone-shaped funnel to receive the fish, which is drawn towards the shore, bringing with it all the shallow and small tuns in their arms, the larger are first killed with poles. This fishery, practiced on the coast of Languedoc, sometimes yields many hundredweights at each sweep of the nets.

Another kind of taking tunny is by the madrigue, or, as the Italians call it, tonnaro. This is a more complicated engine, and somewhat expensive to set up. It consists of a series of long and deep nets fixed vertically by cords at their upper edges, and with lead and stones at the bottom. These are kept in a particular position by anchors, so as to form an inclosure parallel to the coast, sometimes extending an Italian mile in length; this is divided into several chambers by nets placed close together, leaving narrow openings on the land side. These tunnies, which in their progress proceed along the coast, pass between it and the tonnaro: when arrived at the end, they are stopped by one of the cross nets, which closes the passage against them, and obliges them to enter the tonnaro by the opening that is left for them. When once in, they are driven by various means from chamber to chamber to the last, which is called the chamber of death. Here a strong net, placed horizontally, can be raised at pleasure, brings the tunnies to the surface, and the work of destruction commences.

Sailors who have come off in boats for the purpose, give unequal battle on all sides, striking the tunnies with poles and harpoons, or using other similar weapons. This is an event which attracts a great number of curious people to witness it, one of the great amusements of rich Sicilians, and at the same time one of the most considerable branches of the commerce of the sea.

When Louis XV. visited Marseilles in 1724, he was invited to a funny-fishing at the principal madrigue of Morgion; and found the diversion so much to his taste, that he often said it was the pleasantest day he had spent in his whole progress through the south of France.

The tunny is occasionally taken in the British seas, but it can scarcely be regarded as more than a straggler. In the seas of the South of Europe, and especially in the Mediterranean, it is very abundant.

The Bonito (Scomber pelamys) of Linnæus, is also an occasional visitor to the coasts of England, but its true realm is in the tropics. It is a very beautiful fish of a fine blue colour, with four dark lines extending from the pectorals along the side of the belly to the tail. It rarely exceeds thirty inches in length. The Bonito of the Mediterranean, a fish of equal beauty, is a distinct species, and is the Pelamys Sarda of Cuvier. Its back and sides are marked by dark oblique transverse bands. It has much stronger teeth than the Bonito of the tropics.

This Sardine, or sardine, is a small fish, usually esteemed as food and not as fish, covered with small scales, which are used as tests for the powers of microscope glasses. They have long scatognate many-pointed antenna, distinct palpi to the mouth, and moveable false feet on the sides of the abdomen; the body is terminated by artculated sets, three of which are especially conspicuous. The Podereile have 4-pointed antenna, distinct palpi, an abdomen terminated by a forked tail, which is folded under the belly when the animal is at rest, and serves to aid it in leaping. They are little, long, soft insects. The Lepisma and Podereile live chiefly among wood or under stones.

Ticorea, a genus of plants belonging to the natural order Rutaceae. It has a small 5-toothed calyx, a monopetalous funnel-shaped corolla with a long tube, and a 5-angled limb, either equal or unequal. The stamens are from 3 to 8, of which from 2 to 6 are often sterile. The disk is cup-shaped, surrounding the ovary; the stigma 5-lobed. T. jussinifolia is a shrub from seven to eight feet high, a native of Rio Janeiro. The leaves are ternate and stalked; the leaflets large, entire, flat, covered with whitish silver, tapering to the base, acuminate, obtuse, deep green with pellucid dots. The calyx is rather downy, the corolla white, downy, glabrous with pellucid dots. A dejection of the leaves is drunk by the Indians as a cure for fever and inflammation.

This is an insect which is common in many countries, in which whatever is warm, and subject to variations of temperature, it is the more abundant. It is called by the Indians fat and pellucid, from the little pellucid dots in its body. It is a very common insect in the United States, and the species is very abundant in America. T. felipugia differs but little in its character from the last species, but in its stem being generally arborescent, its panicles contracted, its flowers not more than half the size, the bracts more numerous and folaceous, and the style more protruded. The
The Report is accompanied by Minutes of Evidence, an appendix of matters relating to the inquiry, and by plans of the river Thames between London Bridge and Gravesend, the river Blyth, Harwich Harbour, and the river Yare, Rye Harbour.

The Second Report of the Commissioners is dated March 20, 1846. It is printed separately, as well as with the Minutes of Evidence, the whole forming a very bulky volume, with numerous plates. The Commissioners state that a more extended inquiry has fully confirmed the views which the limited examination of the previous year led them to. They find that there is not only a great want of suitable harbours and other appendages to the ports, but that such control, in every one of the numerous cases which came before them, would have been the means of saving unnecessary outlay, of preventing encroachment, which is now scarcely remedied, and of preventing the execution of works which it is now expedient to remove.

The income of the various ports of the United Kingdom considerably exceeds 800,000 a year, the whole of which is levied by charters and acts of Parliament, or otherwise, from dues on shipping and on goods borne by shipping, but over the expenditure of which Parliament has not at present the slightest control. After explaining the causes of the misapportionment of much of this money, the Commissioners detail their proceedings since the First Report.

They state that they have examined the chief ports on the east coast of England from the river Thames to the Tyne; that they have also inspected ports on the south coast, viz. at Chichester, Chichester Harbour, Rye, Rye Harbour, Yarmouth, and Lowestoft; and that they have been strongly impressed by the great value of its national harbours and ports as a means of increasing the trade and commerce of the country, and the extent and capability of improvement of its fisheries, which, even in their present state, with the fishery-port in ruins from neglect, afford employment to 19,880 vessels and boats, and 63,800 herring fishers.

The Commissioners next point out in detail the injuries which have arisen, partly from neglect and partly from mismanagement, and which an efficient control would have prevented, in the harbours Dundee, Weymouth, Plymouth, Chichester, Chichester Harbour, Rye, Ribble, and Dee, and the ports of the Isle of Man; that in Ireland they have visited most of the ports and fishing-places, and that they have been strongly impressed by the great value of its national harbours and ports as a means of increasing the trade and commerce of the country, and the extent and capability of improvement of its fisheries, which, even in their present state, with the fishery-port in ruins from neglect, afford employment to 19,880 vessels and boats, and 63,800 herring fishers.

The Commissioners next point out in detail the injuries which have arisen, partly from neglect and partly from mismanagement, and which an efficient control would have prevented, in the harbours Dundee, Weymouth, Plymouth, Chichester, Chichester Harbour, Rye, Ribble, and Dee, and the ports of the Isle of Man; that in Ireland they have visited most of the ports and fishing-places, and that they have been strongly impressed by the great value of its national harbours and ports as a means of increasing the trade and commerce of the country, and the extent and capability of improvement of its fisheries, which, even in their present state, with the fishery-port in ruins from neglect, afford employment to 19,880 vessels and boats, and 63,800 herring fishers.

They point out the damage which several of the breakwaters have suffered owing to bad construction, and the distress which has been occasioned by the neglect of repairing many of the fishing-ports. They cite as instances of neglect the injury done to Bantry Harbour, Skerries, and Larne, by discharging ballast and stones into them.

After advertising to the necessity for additional lights and beacons on the Isle of Man, they proceed to animadvert on the river Ouse, in East Sussex. In the north-west of England, on the river Lune and the port of Lancaster, on the Ribble and Dee and port of Preston, the river Dee and port of Chester; on the south coast, Salcombe, Dartmouth, and Portsea; and on the north coast, the Tyne and port of Newcastle with North and South Shields, Sunderland, Hartlepool, Stockton-on-Tees, Whitby, Scarborough, Bridlington, Kingston-upon-Hull, Grimsby, Great Yarmouth, Norwich, Lowestoft, Beccles on the Waveney, Blackney and Cleve on the north coast of Norfolk, Wells, near Blakeney, and Harwich Harbour.

It appears, from Parliamentary Returns, that the aggregate debt of the several ports of the United Kingdom, exclusive of docks in the port of London, exceeds 4,000,000, and that consequently one-fourth of the whole harbour-income of 800,000, must be annually appropriated to pay the interest of the funded debt. The port of London is, however, so large that the net revenue is so small, and the sum required for its maintenance is so large, that it is evident that the cost of maintaining it will be very great.

The Commissioners then animadvert on the obstruction and shoals which so seriously impede and endanger the navigation of the Thames between London Bridge and Gravesend, arising from neglect occasioned by the conflicting claims of the admiralty, the Trinity House, and the corporation of the city of London. The Commissioners finally urge the necessity of establishing a Board of Conservancy for the superintendence and control of the management of all the tidal harbours of the United Kingdom. They also point out the advisability of constructing a number of new harbours, which would be suitable for laying down a permanent network of harbours for the United Kingdom. The Commissioners further point out the advisability of establishing a Board of Conservancy for the superintendence and control of the management of all the tidal harbours of the United Kingdom. They also point out the advisability of constructing a number of new harbours, which would be suitable for laying down a permanent network of harbours for the United Kingdom.

form the tesselae, which may be of any required colour, about an inch square, and to combine them into slabs of about eighteen inches square before laying down. In 1840 Professor of Birmigham University invented the oven method of producing a substance similar to, but very much harder and less porous than common porcelain, by subjecting a mixture of potash, fine clay, and fine feldspar, in a dry and non-combustible body, to intense pressure between metal dies, so as to condense the powder into about one-fourth of its natural bulk, and then baking it. This process was first applied to the manufacture of a kind of button which has in a great measure superseded those of bone and mother-of-pearl; being, when well made, beautiful in appearance, and cheaper and far more durable than common buttons. Mr. Blaistow's process has been adopted in the peculiar fitting for making tesserae for pavements, and the manufacture has been commenced by Mr. Minton with every prospect of success. These compressed tesserae are made by a simple but powerful machine, which concedes the material from a thickness of about an inch and one-eighth to three-tenths of an inch, and are then baked in an oven; and it was stated by Mr. Blashfield in an experimental lecture before the Society of Arts (reported in the 'Athenaeum' of 1843, p. 266), that they had been found to bear a pressure of forty tons, and to be proof against injury by frost, some having been tried by plunging them in boiling water and immediately exposing them to a freezing temperature. Blue and green tesselae are imparted by metallic oxides during the baking process; but other colours are mixed with the materials before submitting them to pressure. By this process tesselae are produced of such perfect uniformity of shape, that when fitted together they unite much more perfectly than those used in ancient pavements, in which the beauty is often impaired by bread and irregular lines of cement. In constructing pavements with them, the tesserae are arranged, face downward, upon a smooth level surface, and, when a convenient portion of the design has been thus adjusted, a stratum of Roman cement is laid upon the back, and worked into the joints so as to form a foundation upon which the tesselae are laid in. In the case of Singer's plan this mode of producing tesselated pavements possesses many advantages over the antient plan, in which, a level foundation having been prepared by cramping stones together, or forming a thick floor of stucco or concrete, a layer of plaster was spread to receive the tesselae, which were laid one by one while the plaster continued soft. This method required much time and care to preserve the level, and as that could not be done perfectly, much additional labour was involved in the subsequent rubbing down and polishing of the surface, an operation which, in the case of vitrified cover, would have added much to the expense of destroying their hard surface. Owing to the imperfect fitting of the antient tesserae it was also necessary to spread cement upon the surface of the pavement, in order to fill up the joints and crevices, and afterwards to scrape it off again.

By Proser's process, with the power supplied by an hydraulic press, bricks and other large tiles may be produced, amoug which may be mentioned slabs, inlaid with coloured devices, for chimney-pieces and other architectural decorations.

An extensive collection of specimens of Roman tesselated pavements, in a very large atlas folio, published by William Fowler early in the present century, together with specimens of antient stained glass, is worthy of the attention of those engaged in the revival of this elegant species of decoration, which, though necessarily expensive, has been so much reduced in cost by the introduction of the compressed tesserae, that in some cases tiffs have superseded the use of oil-cloth in the construction of public buildings. The substitution being effected on the score of economy, although sanctioned by a refined taste.

TIMBER, PRESERVATION OF. Whatever other causes may combine to promote the decomposition of wood by the agency of fungi, it is a fact that under certain forms of decay there can be no doubt that imperfect seasoning, by leaving in the pores of the timber a large portion of the fermentable juices always found in recently-felled timber, is one of the most potent agents. There is no process more essential in promoting the durability of wood as it is in lessening the tendency to those changes of form and bulk which so greatly increase the difficulties of the carpenter and joiner. The process of seasoning usually consists in the exposure of the timber to the action of air in a dry situation, in stacks or piles so constructed as to allow the free circulation of air in contact with as much as possible of the surface of each piece; until, if the sap or vegetable juices shall have dried up so far as to offer but little food for the multiplication of the microscopic fungi which constitute various kinds of rot. In order to the success of this operation it is important that the timber should be so arranged that the surface of each piece may be as far as practicable on the ground as to allow the circulation of air beneath as well as above it; and also that, if exposure to rain be not entirely avoided, care be taken to prevent the lodgment of moisture in any place where it is likely to cause the growth of fungi. Improvements in this respect have, of late years, been introduced in our dockyards, in the stacking of timber upon elevated supports of iron or stone, and the building of ships upon similar foundations beneath. In all such cases, where the climate is mild, while they allow an unimpeded current of air around them, in the article Horset, pp. 58 and 54 of this volume, we have noticed a very simple, though not unimportant, improvement upon the common method of seasoning flooring-boards. Kindly, and the expulsion of sap by charring or scorched the surface of the timber, have also been tried, but without success, as substitutes for the tedious operation of natural seasoning.

Another process, which may seem at first sight very unlikely to succeed, and respecting which indeed the most contradictory opinions are given by writers on the subject, is the preservation of timber by lengthened immersion in sea-water, and subsequent drying. Immersion in sea-water especially has been extensively practised of late years; and it is stated that a large portion of the timber in some regions has been preserved in this treatment has arrested, the action of the sea-water appearing to destroy the vitality of the fungi. Some authorities however state that ships built of timber which has been so immersed, as but little consequence of the bygymetric properties acquired by the absorption of salt.

The protecting power of metallic oxides, when applied to the surface of wood in the form of paint, is well known; and many abortive schemes for the preservation of timber have been devised to act upon the same principle, which is that of excluding such external influences as might promote decay. To imperfectly seasoned timber however such applications are worse than useless, because by filling up the pores they impede the natural drying of the vegetable juices, and therefore rather promote than check internal decay. Far more efficient than these are the numerous modes of protection which involve the impregnation of the timber with some antiseptic substance, or with such matters as, by pre-occupying the pores, may render the reception and germination of destructive fungi mechanically impossible. Historical notices of the application of many powerful disinfecting materials are also in 'Mecaniche's Magazine,' vol. xxix. pp. 346-350, extracted from a report made in 1843 by a committee of the Franklin Institute, on the best method of paving highways; and in a paper previously in the same work. (See also our report of an interesting conversation on the subject, at a meeting of the Institute of Civil Engineers, in 1842, when several of the principal modern inventions were discussed. Of plans for protecting timber by impregnation, perhaps none has attained such general celebrity as Mr. Kyan's, which was patented in 1832, and has been very extensively practised under licences granted by the Anti-Dry-Rot Company. The preservative agent in this process is bi-chloride of mercury, commonly called corrosive sublimate, which is dissolved in water, and forced into the pores of the timber, in closed tanks, by means of force-pumps, and which combines with the albumen of the wood, and converts it into a compound and capable of resisting the ordinary chemical changes of vegetable matter. The idea of using corrosive sublimate for this purpose appears to have originated with Mr. Kyan; that substance having been tried and recommended as an anti-dry-rot application by Sir Humphry Davy many years previously. The alleged failure of the precipitate formed by potassium salts of Kyan's having prompted to the action of sea-water, led Sir William Burnside, with the view to preserve timber when exposed to the action of sea-water, led Sir William Burnside, to test the power of preserving timber by immersion in sea-water, and the success of this treatment has been announced. Sir John Barrow has recommended the application of creosote, obtained from the distillation of tar, and applied in the form of gas, by which it may be made to penetrate to the heart of the largest logs. This treatment renders the wood exceedingly hard, so much
so indeed as to render it difficult to work. An oil extracted from
chips and refuse wood was used for the same purpose by
Mr. Macdonochie in 1803. He applied it by placing the tim-
bers in the fire, several of the ashy fragments and ashes
rubbed between the pores of the timber by the admission and subsequent con-
denstation of steam; and, after repeating this process as often as
needful, plunging the timber into the oil, which filled the ex-
posed parts of the wood. Encyclopaedia Brittanica, in a
paragraph which is given under 'Wood-Preserving', in the
'Supplement' to Dr. Ure's 'Dictionary of Arts, '&c., ap-
pears to be somewhat similar, although the impregnation is ef-
chanted by spraying or 'drenching'. Sacrificing the
forcine he injected fluids into the pores by hydrostatic pres-
sure. Dr. Ure mentions the application by this process of
oil of tar and other bituminous matters containing crocoite, and
sulphur of iron, which holds more crocoite in solution than any other water solvent. For railway
sleepers, piles, posts, and fencing, this process has been ex-
tensively and most successfully employed, as timber protected by
it is not affected by exposure to alternate wetness and
dryness; while the commonest and cheapest Scotch fir
is rendered superior to the best and hardest wood in an un-
protected state. In the discussion at the Institute of Civil
Engineers above alluded to the efficiency of coal-tar in pre-
paring ship-timbers was particularly mentioned. It was
stated to be superior to vegetable tar, and its efficacy in
reserving the timber, was ascribed to the sulphurous
bony or sulphone acid, which is highly destructive to
animal and vegetable life. Piles protected with coal-oil were
stated to have resisted the attacks of the teredo better than
those treated with other materials. It is curious, however, to
observe that the coal must be deprived of its ammonia, which
would produce immediate decay if thrown into the timber. In
Mr. Bill's method, tried about 1822, some large logs were
impregnated with asphaltum; and a five years' immersion in
the dry-rot pit at Woolworth showed that timber thus pre-
pared would withstand the fungus-rot, while unimpregnated tim-
ers were destroyed in one-fifth of the time. M. Pallus, in
1779, proposed to mineralize, by steeping it to saturation in
green vitriol, and precipitating the vitriol by means of lime-
water; and in Payne's recent process it is proposed, by the
application of both exhaustion and pressure, to impregenate
wood with metallic oxides, alkalis, or earths, and, by decom-
pozing them in the pores of the wood, to form new and in-
soluble compounds. The writer has seen specimens of wood
which appeared to be almost alkali- or fossilized by this
method, by which the softest woods may be rendered harder and
denser than the hardest in their natural state, apparently
indestructible by any ordinary process of decay, and, for all
practical purposes, incom-bustible. In addition to its anticipated
utility as a means of preserving wood, it may prob-
able be useful in increasing the value of many soft and
rapidly growing woods, by rendering them applicable where
hitherto none but costly woods could be employed. In 1849
Dr. Liebig's studies on the impregnation of wood by
Sciences on the application of pyroligneous iron (which had
previously been used in this country by Mr. Bethell, as abo-
mentioned), or of other metallic salts or earthy chlorides, by a
process which had already been practiced in the
lowering the end of the tree, as soon as it is felled, in the
solution, which is thereby drawn into the pores by what may be
considered as a continuation of the natural process of circula-
ion. Unless performed immediately after felling, the process
will not answer, as the power of absorption becomes very
shortly impaired. Other plans have been tried for effecting
impregnation from one end of the timber, in some cases by
attaching a water-pump to the tree, thus bringing the fluid to the upper-
end, and thus causing the preserving liquid to trickle down
through the substance of the wood, until it drops from the lower
end. In connection with all such schemes it is well to re-
member that the results have been attained with the assistance of
a valvular structure in wood, namely, that if a trunk be ex-
posed to a running stream, with its butt towards the current, its
vegetable juices will be drawn away, whereas if it be laid in the opposite direction.
Dr. Bocherie proposed by his process to fuse such liquids as might prevent dry-rot,
warping, and splitting, such as should reduce the inflammability of
the timber. The process has been proposed to wood by
un-odour; and it is evident that the same objects might be
affected by many of the other modes of impregnation which
have been suggested. Mr. Bushell, for example, proposed, in
one of his patent processes, to coat the outer
of a double glass, which when heated and
protecting film or glaze, impervious to the further action of
fire.

A popular article on the preservation of timber, in which several of the above processes are described, was given in the
'Penny Magazine' for 1844, p. 185; and much information on
the subject is contained in the article 'Ship-Building', and some
other articles of the same kind, in the seventh edition of the
'Time'.

TIME. A reference has been made to this head from the word
FUTURE. Time as expressed by the different forms of
verbs is considered in the article CONSTRUCTION, P. C.

TISSUES, ORGANS AND SUBSTANCES. In the present section we propose to
take a brief sketch of the chemical physiology of the organic
kingdom. We commence with the consideration of the origin of
those substances which are common to plants and to animals,
or which exist in one of them only. The first division
contains protein; the second embraces cellulose in plants, and
gelatin in animals. We shall show that these substances and
their derivatives yield the foundations of the animal and
vegetable kingdoms.

Protein is undoubtedly the most important of all known
substances in the organic kingdom. It is present in all parts
of plants, in roots, stems, leaves, fruits, and in their
several juices; in the animal body it is the chief constituent of
the blood, the muscles, and many other parts, and is the original
material of all the others. Dr. Liebig has shown that,
see Cuzzocras, and in this work he has been directly prepared for the food of plants, and is found in
the youngest roots; whether it is only formed there, and afterwards
conveyed to the other parts, or whether it is produced in any
other part of the plant, is uncertain. Its property of being
readily soluble in water facilitates its transference to the
various organs. It may however assume the solid state and
become deposited in cells; in this form it occurs in many
seeds, occasionally being their principal constituent. This
deposition is effected in a very simple manner. Most
acids render it insoluble, and therefore the mere presence of an acid
is usually sufficient to accomplish the transformation: again,
the insoluble protein may be redisolved by alkalis, and
hence, after it has been deposited in the cells in a solid state, it
may be removed to another part of the plant through the
medium of an alkaline solution.

Whether protein can be formed within the animal body is
uncertain, but it cannot be doubted that the protein
compounds in vegetables are imparted to animals in their food,
and as these compounds form the principal component parts of the
animal body, this constituent must be supplied either wholly
or in part by plants.

The protein-compounds existing in plants were till quite
recently known as soluble albumen, coagulated albumen,
leucin, and gliemin, and given names denoting the
three first the names vegetable albumen, vegetable fibrin, and
vegetable casein, assertering that they are identical in their
physical properties and in their chemical compositions with
the corresponding substances in the animal kingdom. The
discovery of protein, denies the accuracy of this statement.
'The special character of these animal substances is, he remarks,
determined by the small portions of sulphur
phosphorus they contain, by which they differ from each other and
from pure protein. The proportions of sulphur and
the three vegetable substances are still unknown;
and therefore the names proposed by Liebig cannot be applied
them. Moreover, the vegetable albumen and leucin
iffer so much from animal fibrin and cassein, both in form and appearance,
that they ought not to have a similar name.' We
shall retain the former names, representing them as the
substance which is precipitated in white flocks, when the infusion of
crushed peas or beans in warm water is mixed with an
acid.

By soluble vegetable albumen we mean to designate that
substance which, being soluble in water, is precipitated from
the juices of plants by heat, alcohol, or acids. It is soluble
in weak alkaline fluids, from which it is precipitated by acids,
alkalis, and, independently of any other means, by
the same composition as protein. By coagulated vegetable
albumen we mean the compound of protein, sulphur, and
phosphorus which is insoluble in water; it exists in the seeds
of the cereals, by which it is known to be composed,
and the substance which can be extracted by alcohol from

Vol. II. • 4 M
ordinary gluten obtained by washing away the starch from flour. It is the same substance as is described in the article CHEMISTRY, P. C. S., as dextrine. Its composition according to Mulder is 10 (Ca H$_4$ Ni O$_5$) + $S_r + 10$ F + $S_r$; or F + $S_r$.

The protein-compounds contained in the animal body, as far as we yet know, are the following:--

**Fibrin** from blood is composed according to the formula 10 (Ca H$_4$ Ni O$_5$) + $S_r + 10$ F + $S_r$; that is to say, every 10 parts of its constituent materials consist of 10 valents of protein with one each of sulphur and phosphorus.

**Albumen** from eggs has a similar composition.

**Albumen** from the serum of the blood is represented by 10 (Ca H$_4$ Ni O$_5$) + $S_r + 10$ F + $S_r$; that is to say, it differs from fibrin in containing one atom more of sulphur.

**Casein** from cow's milk, 10 (Ca H$_4$ Ni O$_5$) + $S_r + 10$ F + $S_r$.

**Crystallin**, the substance that forms the principal constituent of the lens, 15 (Ca H$_4$ Ni O$_5$) + $S_r + 10$ F + $S_r$.

These are all the protein-compounds of the animal body yet known. The muscular fibre is for the most part composed of a protein-compound, fibrin, which likewise exists in the circulating fluids; and albumen occurs in the blood and other substances of the body in the composition of the blood. The above compounds of protein enter into some very important combinations, a few of which, from their physiological bearings, we shall here notice. The combinations of the protein-compounds of fibrin, albumen, casein, with alkalies, acids, and salts, are especially remarkable. Protein is soluble in weak alkalies, and according to Mulder it exists in the blood in a state of combination with sulphur and phosphorus. Enderlin and the Gieson school, on the other hand, deny that it exists in that fluid as protate of soda. They assert that the cause of the alkalinity of the blood is the presence of the ordinary tribasic phosphates of soda—a salt which has the power of dissolving the protein-compounds: the question whether Mulder or Enderlin be correct is still undecided.

C—neutralizing a weak alkaline solution of protein by an acid, its solubility is greatly diminished; a fact which Mulder regards as elucidating the medical properties of certain acids. The sulphuric and phosphoric acids for instance possess the property of stanching blood; acetic acid, on the contrary, by which protein is readily dissolved, is destitute of that property. Very dilute hydrochloric acid occurs in the stomach, and as it possesses the property of dissolving protein, it doubtless renders the food (at least the portion consisting of protein-compounds) tender, and thus assists digestion. Some acids enter into combination with the protein-compounds, producing comparatively insoluble bodies. For this reason certain vegetable substances and hydrochloric acid are very effective in curturing fevers, scurvy, &c. As an illustration of the combinations of the protein-compounds with salts, we may notice that of bone-earth with casein. Bone-earth is a phosphate of lime and of oxalic acid, and contains, according to the formula 3 P, O$_2$, 8 Ca O. In casein, and therefore in milk, it exists in great quantity, and this seems to supply a large amount of earthy matter to the tender bones of young animals.

In addition to albumen and fibrin, a third protein-compound exists in the blood, constituting the cell-walls of the corpuscles. It is termed globulin. Its real composition is unknown: Simon regards it as casein. All these protein-compounds contain more or less phosphate of lime, which thus finds its way to the bones.

Two other very important protein-compounds exist in the animal body, namely the binucleotone and trinitrogenate of protein. They both exist to a large amount in the blood in inflammatory diseases, and to a small amount in healthy blood. The latter is soluble in water, the former is not. (For the mode of obtaining them in a state of purity, and for the fullest account of them in the English language, we must refer to Dr. Day's Introduction to Simon's 'Animal Chemistry,' published by the Sydneyham Society, London 1845.) At every reaction of the protein in the blood-processes and in the blood-compound and Mulder (who must be regarded as the highest authority in all that relates to protein) believes that they form around the blood-corpuscles a thin layer having the same composition as the albumen or inflammation.

The above sketch is sufficient for our purposes at present. In a later part of this article we shall have occasion to return to the protein-compounds. We now turn to the second group, commencing with the consideration of cellulose, or the cellular tissue or substance. As the morphological properties of these substances have been fully discussed in the article TISSUES, VEGETABLES, we shall confine our observations to the chemical characters and metamorphoses of this substance.

This organic compound may be prepared from all the parts of plants without exception, by dissolving (by certain agents) the other substances associated with it. Pure cellulose is easily obtained from the pith of the elder-trees, or from the spongy vascular vessels of trees, by treating them with acids, peracetic acid, and water, the cellulose, which was previously solid and dense, assumes a spongy appearance. As a proof of its constant composition, it is worthy of mention that the following substances, previously purified in this manner, gave similar results, viz. the ovula of almonds, of apples, of the Helianthus ananassus, the sap of cucumbers, the tissue of the cucumber, the pith of the elder-tree, the pith of the Zaschoyledonea pumila, the wood, the leaves of endive and of Ananthus glanulosus, the tracheum of the Buceas caprensis, films from the pith of oak-trees, cellulose from cow-dung (the cow food with meadow-grass), the internal tissue of the fruit of Agave americana, the succulent of the Physalephas, extracted lichen, membranes of the Chare, &c. From these and various other substances, the purified cellulose always gives a result approximating to the above, it is thus evident that the proper tissue of all plants leaves a substance which is identical for all of them,—a substance which contains carbon and the elements of water, which is insoluble in water and in organic solvents, and which is therefore easily convertible into starch and sugar; and that in its turn it may easily be produced from dextrin (CHEMISTRY, P. C. S., p. 345), the change consisting only in the loss or gain of the elements of water. It has been recently shown by Von Baumhauer (in Mulder's Laboratory) that sulphuric acid or diastase will convert cellulose into dextrin. Hence the cellulose of these plants, being easily converted into dextrin, may fairly be reckoned among the substances which are most serviceable in maintaining the vital functions of animals.

Further, as cellulose exists ready formed in the youngest parts of plants, it belongs, together with protein, to the first and oldest vegetable substances. It consists, according to Mulder, from solid particles or dissolved in the liquids with which their organs are permeated. In plants the cell-walls are composed of cellulose, and the plant-tissue is the composition of cellulose and other substances; in animals, as well as in plants, the cellular substance is the chief agent in connecting all the other existing organs.

Mohr and Nebenlein have shown that the cellular membrane of many parts of plants is coloured blue by iodine, just as if it contained starch. This apparent identity of re-action would
lead us to infer that cellulose can often be modified as if it were into starch, though still retaining the appearance of cellular membrane. The similarity of the chemical constitution of these two substances renders their conversion apparently easy.

For 1 eq. cellulose \((C_{n}H_{2n}O_{n})\) = 2 eq. starch \((C_{n}H_{2}O_{n})\) + 1 eq. water \((H_{2}O)\). Hence, by a separation of water, the starch formed from the cellulose may be converted into starch; and conversely, by the absorption of water, starch may be converted into cellulose.

Dextrin exists in two more or less definite forms: common starch, lichen-starch, and inulin. The first is intermediate between dextrin and cellulose; the second, between dextrin and common starch; and the third, between common starch and sugar.

Of the two forms of dextrin, which are found in the most different parts of plants, and present varying forms in consequence of having to adapt themselves to the shape of the cells in which they have been deposited. It has been frequently observed that starch-globules, after being deposited, again disappear under the influence of growth; that is to say, they become dissolved and carried away to other parts by the sap, and give origin to new products. In young parts of plants, such as the extremities of the radicle, no starch is present, but only cellulose and protein-compounds; hence, it is not formed till after the parts in which it has to be deposited have obtained a certain growth. Payen could not detect any starch-globules in the cellular canals of the young twigs of the birch, nor in the cells of the leaf veins of tobacco, or in the hypocotyls of pea-seeds, as far as the eye of the microscope goes; hence, if starch is present, it must occur in a dissolved state, or in a modified or changed condition. It is further worthy of remark, that in those bulbs in whose scales there is much starch, starch is dissolved when the scales are exposed to light; that is to say, it becomes converted into other substances. This is the reason why much less starch is to be found in the parts of a plant which are above-ground than in the roots, and that in plants whose stalks contain starch it is found chiefly in the pith. We have already mentioned that starch-globules may be dissolved wholly or in part during the growth of the plant. According to Payen the products of this metamorphosis are dextrin and sugar, the carbo-hydrates of action dextrin, a substance the effect of which on starch separates from plants is now well known. This is the change which frozen potatoes undergo when all the starch is converted into sugar. It also takes place in the growth of new potato-plants; all the starch disappearing from the tuber, and being replaced by sugar. According to De Candolle, the quantity of starch in potatoes increases during their ripening almost in the same degree as it afterwards diminishes. In August, 100 lb. of potatoes gave 10 lb. of starch; in September, 14-8 lb.; in October, 14-75 lb.; in November, 17 lb.; it remained constant till the end of February; in April it had diminished to 13-76 lb.; and in May, to 10 lb.

There is still considerable mystery regarding the formation of starch. We have no doubt that it is the result of the respiration of the plant, and it is very certain that the same substances may, under different circumstances, form starch. In addition to its uses in forming dextrin and sugar, it is likewise the efficient agent in the production of fat and of chlorophyll.

Lichen-starch. The starch of the cryptogamic plants has been examined by several chemists, especially by Vogel and Dietrich. It is coloured green by iodine, instead of blue, and in several other points differs from ordinary starch.

Inulin is a modification of starch, very abundant in the dahlie, helenium, and taraxicum, but found also in many other plants. [Chemist. P. C. S. p. 345.] It is very readily converted into sugar, and as it combines with this sugar and carries it with it, it is obvious that ultimate analyses of inulin from different plants must vary. Possessing apparently the same composition as starch, it differs in not being changed by the action of malt, in not being reduced to the blue with iodine, and yellow. It may as well be termed a variety of sugar insoluble in cold water and destitute of taste, as a variety of common starch. From the facility with which it may be converted into sugar it is simply starch consisting of sugar and common starch. In many plants dextrin is a transition substance from common starch to sugar, as is the case when either sulphuric acid or diastase [Chemist. P. C. S., p. 345] is applied. It is here that the starch is converted into sugar, and the blue with iodine, but without formation of dextrin. As its composition is the same as that of cellulose, it is probably produced from that substance and not from starch.

From starch we are led to consider dextrin a very important constituent of plants, dextrin, which is obtained by treating starch with diastase. [Chemist. P. C. S., p. 245.] Mulder has shown that dextrin may also be obtained from cellulose both by sulphuric acid and by diastase. The quantity of diastase required for the conversion of cellulose into starch is extremely minute; if too much be used, or the process continued too long, grape-sugar is produced. It is by these or similar means that nature converts cellulose into dextrin, and dextrin into starch. As in making barley-dextrose in the brewery, if the starch be too strongly devitalized, the reason why it should not in a similar manner be produced in the growing plant, and thus convert the cellulose into dextrin.

The sap of nearly all plants contains a certain amount of dextrin, which, having the same chemical composition \((C_{n}H_{2}O_{n})\) as gum, and in many other respects resembling it, has been in most cases converted into gum, the equivalent of water \((H_{2}O)\) taken from one equivalent of cellulose \((C_{n}H_{2}O_{n})\) is formed. Thus a part of the cellular membranes may be converted into dextrin by catalysts [Chemist. P. C. S., p. 341] without destroying the cells, if the vegetable sap, while passing through them, contains only a very minute quantity of diastase, or of a substance resembling it.

We have already mentioned that gum and dextrin have been frequently confounded. The most important difference between them is, that the latter may be changed into grape-sugar by sulphuric acid or diastase, while the former is incapable of undergoing this change.

Dextrin belongs to the nutrient matters; all the starch taken as food being converted by the gastric juice into it. The gums are mere excrescences, and are apparently of little or no importance in part or altogether of the cells.

There seems every reason for believing that dextrin is the source of the cellular matter, for it is a universal constituent of all parts of plants. We are justified in assuming that the formation of starch and cellulose is a very common process in a state of solution, so as to be able to penetrate through the cell-walls, and to supply new substance to increase the number of cells. No material but dextrin is fitted for this office, thought in young organs sugar also contributes to it. By the production, during germination, of dextrin and sugar, we are led to believe that the cellulose of the young plant is really formed from this dextrin and from the sugar in the germinating cotyledons. While many full-grown plants do not contain sugar, all contain dextrin, so that the use of the latter in the formation of cells cannot be doubted.

Dextrin is not merely a source of cellulose, but likewise of starch, sugar, gum, and perhaps other vegetable substances; it is almost as valuable to plants as protein is to animals, for it is a constituent from which their organism derives its most important products. The composition of dextrin being \(C_{n}H_{2}O_{n}\), the formation of cellulose is accomplished by every two equivalents of dextrin taking up one equivalent of water. Thus

\[
2 (C_{n}H_{2}O_{n}) + H_{2}O = C_{n}H_{2}O_{n} = \text{cellulose.}
\]

Starch and gum contain the same elements in the same proportions as dextrin, and hence for their production require merely a re-arrangement of the molecules.

Sugar, as we shall immediately show, requires only the addition or subtraction of water from the elements of dextrin.

The different species of sugar, as far as they are yet known, are—

Milk-sugar is an integral constituent of the milk of the mammalia, and has very rarely been met with anywhere else. It has recently been detected in eggs during the process of incubation; but this observation requires to be confirmed. Case-sugar is the most closely related to dextrin differing from them merely by one equivalent of water. It is not by any means so widely distributed as grape-sugar, being found in very few plants besides the sugar-cane, beet, and canna. Grape-sugar is identical with the sugar of the grape, and in diabetic urine, and with the glucose or fruit-sugar of the French chemists. The uncrystallizable sugar which is obtained during the decomposition of many plants, and which is yielded by starch on being acted upon by diastase or sulphuric acid, has the same composition as grape-sugar.

Eucalyptus-sugar is a species of manna produced in Van Diemen's Land by various species of eucalyptus. Whether it...
TIS 636 TIS

is the natural sap spontaneously escaping, or whether it is the sap extracted by the locust and afterwards excreted, is un-
certain. Its property has been carefully examined by Professor Johnston of Edinburgh.

There is obviously an intimate connexion between these different kinds of sugar, as cellulose, starch, demineralized, and gum. They all contain carbon, in combination with the elements of water. As they all contain C₄₈, or a multiple of it, they are produced from each other by a simple change depending on catalytic force. [Chemistry, P. C. B., p. 341.]

If sulphuric acid is allowed to act on gelatin, a species of sugar containing nitrogen, and termed glyccidol or gelatin sugar, is formed. The formula is C₂₀ H₄₁ N₂ O₅; and it is worthy of remark that if from two of its equivalents we deduct one equivalent of cane sugar, we obtain the elements of two equivalents of urea, or

\[ \text{C}_₂₀ \text{H}_₄₁ \text{N}_₂ \text{O}_₅ \rightarrow \text{C}_₈ \text{H}_₄ \text{N}_₂ \text{O} \rightarrow \text{H} \quad \text{or} \quad \text{C}_₂ \text{H}_₄ \text{N}_₂ \text{O} \]

This relation leads to the belief that sugar is a component part of the gelatinous tissues, and when separated from them it may be presumed to discharge the same functions as when either cane or grape sugar is supplied with the food. In other words, there exists in the substances yielding gelatin a primary matter which also exists in cane-sugar. If then substances or tissues containing gelatin are employed in effecting the conversion of diastase continually operating in the animal body, this primary matter may serve the same purpose as cane-sugar when supplied to feed the body. On these grounds Mulder considers that gelatin in the alimentary canal should be classed among the soluble sugars.

If gelatin be formed in the animal body, then sugar, either derived directly from the food or produced from starch in the alimentary canal, may be used in its place.

It is not known in what part of the plant sugar is formed. Mr. Knight states that birch sap contains more sugar the farther from the root it is collected; this proves to show that the sap, which probably contains much dextrin, is changed into sugar as it passes through the cell-walls. When sugar accumulates in certain parts of a plant, it almost always remains in solution; it is however found crystallized in some few instances, as in the seeds of Fritillaria and Nigella. Closely allied in its chemical composition to sugar is a peculiar substance which is termed mucilage is given. Although insoluble in water, it assumes the appearance of a mucilaginous mass when immersed in that fluid. It sometimes accumulates largely in certain parts of plants, as in the periderm of quince-seed, lint-seed, &c.; it is the chief constituent of the gums tragacanth and bassonum, and is abundant in various roots, as for instance the mallows. According to Mulder's analysis it must be represented by the formula C₄₀ H₁₅ O₅. It has been shown by Schmidt that mucilage when digested with dilute sulphuric acid is converted into sugar. There is a close analogy between the following series of analogous substances:

Grape-sugar and fruit-sugar \[ \text{C}_₄ \text{H}_₈ \text{O}_₄ \]

Cacao sugar, sucrose, and inulin \[ \text{C}_₁₂ \text{H}_{₁₈} \text{O}_₉ \]

Starch, dextrin, gum, inosuline and inulin.

lichen-starch \[ \text{C}_₄ \text{H}_₈ \text{O}_₆ \]

Mucilage, milk-sugar, and cuculapta-sugar \[ \text{C}_₇ \text{H}_₆ \text{O}_₆ \]

Cerneine \[ \text{C}_₈ \text{H}_₄ \text{O}_₄ \]

In its physical characters the product of the mucous mambrane of the vegetable body resembles vegetable mucilage. Owing to its insolubility in water, both these substances serve to cover denuded parts of animals, and thus are both well suited to lessen or prevent the influence of acrid matters on the tender parts of the animal frame. It is for this reason that the mucilage of sandle, tragacanth, &c. may be made, in certain proper conditions, to supply temporarily the want of animal mucus. In chemical composition they are perfectly distinct, as animal mucus contains nitrogen. The mucus of the animal body seems however to differ according to the organs by which it is produced. (Daily edition of Simon's Animal Chemistry, vol. ii. p. 78, note.)

We now arrive at a peculiar group, occurring both in the vegetable and animal kingdoms—the fats.

Sesame, maragia, and olein are the most widely distributed fats in the organic kingdom, but they are not the only ones. They were formerly regarded as salts formed by fatty acids with glycerin. [Cowper, F. C. S., p. 344; recent investigations have however shown that this view requires a slight modification. Bernouci thinks that glycerin does not exist ready formed in the neutral fats, but that it is a product of the formation of soap; and he considers the base of the neutral fats to be the oxide of a radical (C₃ H₆) which is known lypile. Glycerin is then formed from two equivalents of water (C₂ H₄ O₄) + 3 H₂ O = C₃ H₈ O₆. (If to this we add one equivalent of water, we obtain the formula given in Chemistry, P. C. B., p. 344.)

According to this view, which is supported by Redtenbacher, Vaurrent, and Mulder, the base of every neutral fat yielding glycerin is a compound which is represented by C₂ H₄ O₂.

The most important of the fatty acids are:

- Stearic acid \[ \text{C}_₈ \text{H}_{₁₄} \text{O} + \text{H} \text{O} \]
- Margaric acid \[ \text{C}_₈ \text{H}_{₁₂} \text{O}_{₂} \]
- Oleic acid \[ \text{C}_₈ \text{H}_{₁₀} \text{O}_{₃} \]

These are universally diffused in plants and animals; and, combined with the oxide of lypile (C₃ H₈ O₆), they form the natural fats—stearin, margarin, and olein; and this is the form in which they mostly commonly occur in the organic kingdom. Sometimes however a more powerful base (potash, soda, &c.) removes the oxide of lypile, and there are formed compounds of the fatty acids with alcalis.

In connection with this subject Mulder observes that when salad-oil is conveyed into the stomach, it may pass unchanged into human fat, for both consist of margarin and olein, although in different proportions; and as margarin and olein are found in many vegetables used for food, nothing is simpler than to assume that these substances are directly transferred, without change, into the fats of the animal body.

But if these same vegetables are eaten by a sheep, the same olein and margarin may undergo some change in the animal, since mutton-fat contains a large amount of stearin.

In this case the change is easily understood. For 2 eq. of margaric acid \[ (\text{C}_₈ \text{H}_{₁₂} \text{O}_{₂}) \] = 1 eq. of stearic acid \[ \text{C}_₈ \text{H}_{₁₄} \text{O} + \text{H} \text{O} \] = 1 eq. of oleic acid \[ \text{C}_₈ \text{H}_{₁₀} \text{O}_{₃} \].

Thus, from two equivalents of margarin acid, one equivalent of stearic acid is produced, and one equivalent of oleic acid is given off. In all probability, such a degradation of the margarin acid in the food of the sheep is really effected; and on the contrary, when mutton-fat is used for food by man, stearic acid is most probably converted into margarin acid by the absorption of oxygen. It is now believed by our first physiologists that neutral fats are not directly form fatty tissue, but that they enter the blood in aaponified state. In fact the alkaline character of the bile as it enters the duodenum renders it impossible for the fat to enter the blood without undergoing this change. If it is aaponified, we readily understand how compounds of fatty acids and soda should exist in the blood and in various parts of the body. When a soda-soap however exists in the blood, it cannot form a neutral fat, except bapanified or olein, without combining with glycerin. This leads to the inquiry, in the first place, whether these soaps meet with glycerin; and secondly, if they do, whether the glycerin would combine with the soap and form neutral fat. Here is a strong reason for believing that both these questions may be answered in the negative, for the glycerin set free when the soaps-soap is formed most probably at once decomposed; and further, glycerin will not remove the soda from the fatty acid and form a neutral fat.

It has been suggested by Mulder, that although glycerin will not remove the soda from the crude lypile in a nascent state may do so, and that in this manner the fatty acids may be converted into neutral fats and deposited in the cellular tissue and other parts of the body. We have already shown (according to the opinion of Berzelius) glycerin is the oxide of the radical (C₃ H₆) lypile. The second oxide of this radical exists in lactic acid, which is supposed by the great majority of chemists to be present in most parts of the body. When lactic acid (C₃ H₄ O₃) is sublimated, we obtain a white sublimate, the composition of which is C₃ H₄ O₂; while the composition of the oxide of lypile is C₃ H₆ O₆.

It may happen that there are causes of dioxidation at work in the system, by which some of the substances usually converted into lactic acid are made to produce oxide of lypile, which in the nascent state unites with the fatty acids, forming neutral fat.

Hence in all probability the neutral fats are not deposited directly and unchanged in the cellular tissue, but are first saponified, and entering the blood as maragia and oleate of soda, are again reduced to neutral fats by the influence of lactic acid.

In many parts of plants, especially in the periperia of some fruits, a fatty matter (popularly known as wax) occurs. It has been known to exist in plants, but it has only recently
been shown that bees can prepare it from honey, which does not contain any fat, and plants their beautiful purple bloom; it abounds in the skins of apples, and is a component of the green colouring matter of leaves (chlorophyll), of which we shall presently speak. It is an oil, which collects on the surface of the sugar-cane, and to which he has given the name ceresia. He mentions an important peculiarity in connection with it, namely, that those kinds of sugar-cane which contain much sugar give this oil, whereas conversely, those which contain much ceresia have but little sugar. From this we should infer, that either wax is used in the plant to produce sugar, or sugar to form wax. That this is a very important point he makes evident by the following experiments of Gundisch. He fed bees with a solution of sugar-candy in water, and saw them producing wax. Thus the sugar-cane and bees are both enabled to convert sugar into wax, that is, into a fatty matter.

There are some animals, just as there are some plants, which contain peculiar fats; there are even separate organs in which certain fats are formed.

In order to find the following acids, chiefly in combination with the cavity of the skull of the Physother macrocephalus; phcenine, in the fat of Delphinas phoca; cholasterin, in amber; and the haem of known as alacron-fats known as album; cerebro, cephalol, and steacozoacet—are illustrations of this class.

It is worthy of observation, that both in the vegetable and the animal kingdom there seems a connection between the protein-compounds and fat: when we find solid protein-compounds deposited in plants, we often find at the same time a large quantity of fat, as in numerous seeds; the brain and milk serve as illustrations of the same point in the animal kingdom.

The next question for our consideration is the formation of fat—a subject which has given rise to much angry and intemperate discussion between the leading chemists of France and Germany. Dumas, who was regarded as the representative of the French school, maintains that all the fat of animals originates in and is obtained from plants; while Liebig, on the contrary, maintains that a portion of it is formed by the animal itself, from starch, sugar, and gum. The goose was the animal respecting which the dispute originated. When fattened with Indian corn, the starch must, according to Liebig, have been changed into fat, because he had found but a minute quantity (about 1 part in 600) of fat in that kind of grain. Dumas, however, extracted 9 percent fat from Indian corn (or ninety times as much as Liebig), and thus he found in the food which the goose had eaten much more fat than was present in the fat of the animal itself. For Liebig himself admits that the amount of fat in this grain is so variable that no conclusion can be drawn from the experiment. Liebig quotes many examples of substances which, although they contain little fat, are well known by experience to be especially fit for fattening the animal body. Rice, peas, beans, and potatoes all contain much starch; yet rice gives only 0% to 0.1% of fat, of the peas 0.5% to 0.6% of fat, and of potatoes 5% to 6% of fat. Any animal that has eaten 1000 pounds of one of these substances may obtain from it 2 to 3, 12 to 21, 7, or 8% pounds of fat respectively. He makes the following calculations:

Three pigs were fattened in thirteen weeks require 1000 pounds of peas, and 6525 pounds of boiled potatoes, the latter being equal to 1630 pounds of dry potatoes. These contain in all 26 pounds of fat, the peas yielding 21, and the potatoes 5 pounds. One fattened pig gives on an average 50 to 55 pounds of fat, the three yielding 150 to 165 pounds. Each pig before fattening contains on an average 15 pounds of fat—i.e., 54 pounds for the three. If to these 54 pounds be added 26 pounds contained in the food, we get 80 pounds; and if we subtract these from 150 to 165 pounds, there is a remainder of 70 to 115 pounds, or 35% to 40% of the fat, of the food. Liebig's opinion is further strengthened by the circumstance that some fats are undoubtedly produced in the body, as, for instance, the fats peculiar to the brain, cholestearin, cetine, phcenae, &c. To obtain these from other fat requires just as much new arrangement as if they were produced from starch; hence, in a scientific point of view, there is nothing improbable in the supposition that animals are able to produce fats.

With regard to the presence of fat in plants, it is worthy of observation that all seeds which yield oil on pressure—as the castor-oil seed, hemp seed, &c.—contain starch in their early stages, this starch disappearing as the oil increases, and when the seed is completely developed is not trace of the starch remaining. This renders it probable that these fatty matters are formed from starch. From their ultimate composition it is obvious that whenever fats are produced from any substances that are subject to the action of high-oxidised compounds, or else that oxygen must be itself liberated. Liebig observes that if from the formula for starch, C₆H₁₂O₆, we take 9 equivalents of oxygen, there will remain in 100 parts

\[ \text{C₆H₁₂O₆} \rightarrow 9 \text{O}_2 \]

The empirical formula for fat which comes nearest to this is C₃₀H₄₆O₆, which gives in 100 parts—

\[ \text{C₃₀H₄₆O₆} \rightarrow 36 \text{O}_2 \]

According to this formula an equivalent of starch, in order to be converted into fat, would lose one equivalent of carbonic acid and seven equivalents of oxygen (expressed in symbols)

\[ \text{C₆H₁₂O₆} \rightarrow \text{C₆H₁₀O₆} + 7 \text{O}_2 \]

The same point is also clearly shown by contrasting the ultimate composition of starch and fat.

To 7 equiv. of starch 84 70 70
Add 8 equiv. of water 8 8
And we have 84 78 78

Which are equal to
1 equiv. of marag acid 34 34 3
1 equiv. of oleic acid 44 44 4
2 equiv. of oxide of lypil 6 6 2
69 equiv. of oxygen 69

Making as before 84 78 78

There is a substance almost universally diffused through plants, which we must here notice, and that is, the green colouring matter or chlorophyll. For the following account of this substance we are almost entirely indebted to the investigations of Mulder. It is a striking fact that young leaves have a much lighter green colour than those which are older, showing that the quantity of chlorophyll increases with the age of the leaves. If chlorophyll were a substance poor in oxygen, and were derived from substances rich in oxygen, this fact alone would be sufficient to explain the matter which the green parts possess of separating oxygen. This however is not the case; chlorophyll is rich in oxygen. Nevertheless the leaves give off oxygen not because they are green, but whilst they are becoming green.

When green leaves are digested with ether the liquid becomes green. On evaporating the ethereal solution, and treating the residue with hot alcohol, a considerable amount of white fatty matter (wax) separates on cooling, while the green colouring matter remains in solution. Before proceeding to the consideration of the green colouring matter, it will be expedient to say a few words respecting the mixture it forms with the wax.

In a physiological or botanical sense this mixture has the name of chlorophyll; in a chemical sense the term is restricted to the active green matter. To prevent confusion the former is designated as B. chlorophyll; the latter by C. chlorophyll; B, indicating the botanical, and C, the chemical signification of the word.
We find similar mixtures of a waxy fat, and colouring matter, in other external parts besides the leaves, namely in the petals of the flowers, in the sepals, and in the calyx; and when digesting them in ether we obtain a large quantity of waxy matter in solution, varying in tint according to the colour of the skin; being grey when obtained from apples, and of a brownish or orange colour when obtained from the berries of the mountain ash.

The degree in which the action of light contributes to the change of colour in the C. chlorophyll which exists in the pericarp of tomatoes and the production from it of the colouring matter of the skin of ripe fruits may be obviously inferred from the green colour which such fruits retain if they do not receive a sufficient supply of solar light, or from the difference of colour produced by the opposite side of the same fruit, as well as from the fact that leaves when deprived of the action of light become colourless, while if completely exposed to its action they become a considerable amount of B. chlorophyll.

This apparently anomalous difference in the action of light on the skins of fruits and on leaves is dependent on the same cause as the change of colour in the leaves during autumn; namely, that light not only produces B. chlorophyll when there is a sufficient supply of materials for its renewed formation as often as the existing quantity is decomposed by the influence of the light; and that as soon as this supply is exhausted the green colouring matter is itself decomposed, and other compounds are formed from it.

Light acts powerfully in keeping plants green, and likewise exerts a powerful decomposing action upon all colouring matter, whether chlorophyll be present or not, thus, as we have seen, potatoes, young leaves, &c., become green whenever they are exposed to light, and hence there must be a substance widely diffused through plants, which causes the production of chlorophyll, and which takes place not merely on the surface, but to this extent, as far as it can penetrate through the translucent parts. A full explanation of this phenomenon must be considered part of the action of light, and it is known that the absorbed light is not the only factor involved in the process. Hence, while we may conclude that in these plants or parts of plants, the materials yielding chlorophyll are absent. We may sometimes observe, in sunlight, one single spot of a green leaf, colored red by the action of insects, or by being injured by hail; the green colouring matter is at the spot decomposed by the light; no new portion is formed, and the spot acquires the same colour which the whole leaf would have assumed in autumn. From this we infer that the change of colour in the leaves during autumn is simply dependent on a chemical alteration of the green colouring matter by light.

Mulder, after showing from a large number of facts that wax along with a green colouring matter exists in leaves and unripe fruits,—wax with a red colouring matter, in the red leaves which appear in autumn, and in the red fruits,—and wax with a yellow colouring matter, in the yellow leaves of autumn, and in the yellow fruits, gives a lengthened chemical description of chlorophyll, for an account of which we must refer to the original work.

In another's experiments, and those previously instituted by Berzelius, it appears that the green colouring matter of the leaves is readily decomposed into three different substances, one yellow, another blue, and a third black; and that according to the proportion of these three mixed with the green, a different kind of green must be produced. Hence the difference in the green colour of different leaves depends not only on the presence of more or less chlorophyll, but also on the different mutual proportions of these three colouring matters.

The quantity of pure C. chlorophyll contained in the leaves is exceedingly small; according to Berzelius, it is not more than the amount of pigment in dry cotton.

If pure chlorophyll is added to the action of the sun, the green color becomes in a few hours converted into a yellow. When a solution of pure chlorophyll in ether and hydrochloric acid was kept for five months in a bottle half full, the entire chlorophyll was changed into yellow. From this experiment we learn, first, that the green colouring matter is decomposed and a yellow one left, both with and independently of the influence of light; and secondly, that all probable similar decomposition (accompanied by a reproduction) of green colouring matter and green leaves is constantly going on under the influence of light. Mulder concludes that the colour of decomposed green chlorophyll is not essentially in part the origin of the wax, since the quantity of the latter is found to have increased when the same leaves are analyzed later in summer. In consequence of the continuance of this reproduction the leaves remain green; when it stops, the leaves become yellow, as in autumn.

It is generally supposed that chlorophyll yields a blue colouring matter; it is this which is no doubt present in the skins of many fruits, as for instance those of the grape; the exact nature of the chemical change is not clearly understood.

It is very obvious that the influence of light will convert starch into chlorophyll. Every part of an amylaceous root becomes green on exposure to light. The parts of plants which become green (without exception) contain starch; and in autumn as this green colour decreases, the starch also decreases, and finally cannot be detected by the iodine-test. Hence the greenness of leaves is the same, whether the influence of light; the B. chlorophyll being a complex substance consisting chiefly of wax. The change of starch into botanical chlorophyll may be explained in much the same manner as its conversion into fat.

The wax contained in the leaves and other parts of plants may be chemically represented by the formula C_{54}H_{10}O_{8}. Now if no other products are simultaneously produced we may suppose the wax obtained from the starch in the following manner:

\[\text{5 equiv. of starch} \rightarrow C_{54}H_{10}O_{8} \text{ With 10 of water} \rightarrow C_{54}H_{10}O_{8}\]

Make \[\text{C}_{54}H_{10}O_{8}\]

And 4 of wax \[\text{C}_{54}H_{10}O_{8}\]

Leaving to be given off \[O_{8}\]

That is to say, 5 equivalents of starch yield 4 equivalents of wax, and give off 66 equivalents of oxygen. This fully explains the phenomenon why plants while becoming green, evolve oxygen, and further indicates the use of starch in the leaves.

Mulder has, as far as we are aware, made only one ultimate analysis of pure C. chlorophyll—that from poplar leaves; from this analysis he calculated the formula C_{49}H_{9}N_{O}. Properly speaking, 'Mulder observes,' the green colouring matter in the leaves has nothing to do with the evolution of oxygen; on the contrary, the colourless C. chlorophyll, which seems to be everywhere present, becomes green by the absorption of oxygen. Hence a small portion of the oxygen produced from the conversion of starch into wax is employed for this purpose, and is not mixed with the atmosphere. But this is just the reason why C. chlorophyll is not formed by the exhalation of oxygen; it only becomes green instead of white, as it previously was. This can only happen when there is an abundance of oxygen, and it has been seen to be the case when starch is converted into wax. We may therefore assume as proved that white chlorophyll diffused throughout the whole plant, will become green in proportion as starch is converted into wax, with a corresponding reproduction, to take up oxygen—to become oxidised, just like white indigo.

Now, the probable composition of green chlorophyll, C_{49}H_{9}N_{O} shows that pure white chlorophyll is not produced in the plant. It is necessary, then, if we assume that in a liquid state, should penetrate into the globule of starch, which during this transformation into wax is converted into C_{54}H_{10}O_{8}. We do not know yet what that substance is, but it is certain that it must be one which is diffused throughout the plant like starch; hence it is probably protein, which is changed into a most beautiful violet-coloured substance by the influence of hydrochloric acid and oxygen.

We now return to the animal kingdom, and have a few remarks to offer on gelatin, a substance yielded by most parts of the animal body. Amongst the component parts of organized bodies, the most frequent is the cell. Modified in an infinite variety of forms, it gives rise to the innumerable varieties exhibited both by plants and animals, in the external form, the structure, and consequently the functions of their organs. In the vegetable kingdom the substance employed in the construction of these cells is cellulose combined with a little protein. In the animal kingdom the case is very similar, although the elementary form of the tissue and its chemical characters are different. In animals we must distinguish between the persistent and the original cellular substances. The original in all probability varies in different cases, while the persistent exhibits a constant and general character. The persistent is consequently a secondary product, and in this respect differs from the cellular substance in plants which is a primary or original one; neither has it an actual cellular form like the latter. There is however a resemblance be-
between the two in several points, especially in relation to the large proportions in which they both exist, and to the several functions which they perform. Gelatin is more or less widely diffused over the body, and it would exhibit the entire shape of the principal organs, even if all other constituents were separated. It constitutes the skin, the membranous covering of the mucous membranes, and the spongy portion of bone, and many other substances. It is insoluble in cold water; acetic acid renders it transparent and bulky; and in boiling water, and when hydrolyzed, it acquires the last property that it has received the name of gelatin. The gelatinous substance (skin, vascular tissue, serous membranes, &c.), is insoluble in cold water, and on boiling is merely physiologically changed, although its properties, according to our present means, are nothing taken up and nothing separated; the alteration being similar to that undergone by starch when heated in water.

The composition of gelatin is represented by the formula 4 \( C_2 H_2 N_3 O_4 \) or \( 4 \). Whether obtained from cartilage, from isinglass, or from silk. Both boiled and unboiled cellular tissue (after its conversion into glue) combine with tannic acid, and produce compounds which are insoluble in water and resist precipitation; hence the power of all medicines containing this substance to heighten the tone of the system. The protein-compounds in a similar manner form hard and coherent compounds with tannic acid. For this reason, and for the frequent observation that the above-mentioned other astringent medicines produce compounds of this nature in the organism.

Boiling gelatin water for a long time we obtain a mixture, which is no longer gelatinous; its composition is 4 \( (C_2 H_2 N_3 O_4) + 8 \) or 32. This peculiarity should be remembered, for the compound is likely to be formed in the preparation of broth, and in the preparation of Papin's Digestor to be looked for; and it is regarded by Mäder as doubtful whether this hydrated gelatin can be again converted in the organism into nutritious matter, and whether it may not produce noxious substances in the body.

As gelatin has never yet been discovered in the vegetable kingdom, there is every reason to believe that it is produced in the animal body. It is most probably formed from the decomposition of the protein in the blood, through the action of the alkali in the serum, and the oxidizing influence of the atmosphere.

We are likewise imperfectly acquainted with the products of the decomposition of the gelatinous tissues in the body. Out of the body we know that by the influence of oxidation on gelatin prussic acid is formed, and that, by the action of alkalis, gelatin-sugar, lecose, and extractive matters are produced, while ammonia is disengaged, and an alkaline carbonate formed. Finally, when boiled in dilute sulphuric acid it yields extractive matters with either gelatin-sugar or lecose. Since lecose is also produced from albumen when decomposed by heat, we possess an intimate connexion between that protein-compound and gelatinous matters.

Besides the gelatin obtained from cellular tissue and serous membranes there is another kind which has many of its properties different from the former. It was first described by Müller under the name of chondrin. It is obtained from the cornea, and from those cartilages which do not ossify, by boiling them in water.

The preceding observations on the general organic substances which exist in the two great departments of the organic kingdom are sufficient for the clear understanding of the forms and properties of the elementary parts of plants and animals. Both kingdoms however contain an immense number of additional substances. In plants there are acids, bases, coloring matters, oils, and resins; in animals there are the various secretions. As these vegetable products have been fully treated of in many of the articles of the *Penny Cyclopaedia*, our attention will in the future part of this article be chiefly confined to the animal products.

It is generally admitted that after gelatin has been dissolved, albumen contains about 8 per cent., and gelatin containing 4 per cent. of sulphur. This is very nearly the amount of sulphur which forms for chondrin given in the text, and which is deduced by Mäder from his own analyses.

* Likely has recently found that albumen, fibrin, and casein contain more sulphur, about 20 per cent., when boiled and casein contains 4 per cent. of sulphur. This is very nearly the amount of sulphur in the formula for chondrin given in the text, and which is deduced by Mäder from his own analyses.

**Section II.** Microscopic Character of Tissues.

All organic beings, according to the cell-theory, are composed of a number of minute parts, which in their leading characteristics are identical in the two kingdoms, but which are variable, and whose organic composition is distinctly not only in the animal and vegetable world, but likewise in the different organs of the same animal or plant. These minute parts, which are invisible to the naked eye, although they are found in the vegetable kingdom, are only visible through the microscope in the vegetable, and are known by the term cell. The animal kingdom is more abundant in these minute organisms, which have the most curious combinations and functions. All the tissues that we meet with both in the animal and vegetable world are nothing more than groups of these elementary parts; their functions depending on the nature of the grouping.

The elementary forms which organic matter on becoming organized assumes, are for the most part, if not always, minute vessels which can only be distinguished by the microscope. These have received the names of cellulectomes, or primary cells. They are most easily observed in vegetable and animal tissues in the process of development. They usually contain a fluid, but granules are also set up, and develop in every part of the body, which gives the organism wherein a nucleus is often observable. This nucleus is almost invariably present in animal cells, whilst it can only be distinguished in the young cells of plants. From these simple cells, slight modifications of the elementary forms are constructed; we find them in the blood (blood-corpuscles), in the lymph, in mucous and pus, and in every solid part of the animal body.

The cell-theory in relation to the vegetable kingdom has been already noticed in the article Tissue, Vegetable, F. C., our observations will be entirely confined to the cellular formation and structure of the animal world.

On the addition of acetic acid the cell-wall dissolves while the nucleus remains unacted on; hence the nucleus is regarded as a distinct body. It is named by Schleiden the cytoblast (source, a cell, and βλάστειν, I cause to bud), being supposed by that physiologist to be the originator of the cell. In the nucleus we can usually observe one or more dark spots which have received the name of nucleoli. The nature of these nucleoli is unknown; we cannot tell whether they are cavities, vesicles, or solid particles. They lie on the inner part of the nucleus.

The nucleus itself is regarded as a minute cell; it is connected with the cell, and is an essential element of it.

The cells are surrounded by a fluid whose consistency increases with the age of the tissue, and which finally becomes solid, forming intercellular substances. The cell-tissue takes places in the following manner. In an amorphous, semifluid, sometimes almost gelatinous mass which is named the cytoblastema, and wherein the substances necessary for cell-formation are contained, there is a rapid formation of minute rounded granules (nucleoli), around which is deposited a layer of granular matter, which gradually becomes thicker and forms the nucleus. On the surface of this nucleus a vesicle arises, resembling a segment of a sphere. This vesicle is thin and transparent, at first smaller than the nucleus, but rapidly enlarges, and when it has attained its full size, the nucleus is seen as a minute body attached to its inner wall. The substance necessary for the formation of the vesicle is yielded by the cytoblastema. The earliest trace of organization is coincident with the appearance of the nucleus, which gives rise to the formation of a deposit of granular matter around it, and in this way to the production of the cell.

This theory of cell-formation, which is supported by Schleiden and Schwann, proceeds on the assumption that in cells there is always a pre-existing nucleus. It is objected to by Henle and others, on the ground that there are cells in the vegetable kingdom in which there is no nucleus, or in whose nuclei there are no nucleoli; as for instance in the cryptogamia; and according to Meyen also in many phanerogamia. Similar objections have been made to cell-theory in the animal kingdom, but Schwann combats the objection by the assertion that the nucleus or nucleoli become absorbed during the development of the cell.

According to Schleiden, the membrane of the cell grows from the nucleus, which latter remains as a persistent part of
the cell-wall; Mohl opposes this view, asserting that the nucleus lies within the cell at some distance from its mem-
brane. Fig. 1.

An ideal figure illustrating the formation of a cell. In an amorphous substance (A A), the protoplasts lie, three ideal cells (B, C, D). The cell B appears as a hollow and in the cavity of the cell, a fluid which escapes observation. The cell C is round; it contains a nucleus with a single nucleus in its centre; the cavity is filled with dark granular matter. In the cell D the nucleus lies on the inner surface of the cell-wall; no nucleus is observable. The latter form is very rare in the vicinity of the nucleus, but fluid and invariable in the remainder of the cavity.

Valentin has also made similar observations in many of the animal tissues. He has observed cases in which the nucleus was not directly connected with the cell-wall, except by a few radiating fibres. Hence the function of the nucleus in relation to cell-formation is still obscure.

Whenever cells are formed, numerous pro-existing nuclei are always present. They serve to form the contents of the cell, while the cell-wall is probably formed from the delicate connecting medium which unites these minute granules. These granules, which are the most minute organised particles with which we are acquainted, must be regarded as the most elementary form of all organic structures, since they are a necessary condition for cell-formation; there can be no doubt that they contain a protein-compound, since in the most recent structures in the animal and vegetable world protein is never absent, and indeed appears to be essential to organization.

The very simplest form of fungi (such as the common mould-plant) which is produced in non-nitrogenous bodies, such as lactic or tannic acid under the influence of the atmosphere (and therefore of nitrogen) and of water, contain protein from the first moment of their existence or of their mother. The bodies of the primary and germinal membranes.

This structure receives the former name from its being the foundation or resting-place for the epithelium-cells which cover its free surface, whilst the latter appellation was selected because it is a form of the primary cells of glands, and the source of secondary or secreting-cells. Bowman considers it to be simple or homogeneous. This is true as far as it contains no blood-vessels, and as regards its external and attached layers; but as in its original condition it consists of cells, and when perfect contains nuclei at equal or variable distances, it must not be considered as simply molecular.

Germinal membranes, observes Goodier, are only met with on the free surface of parts or organs. One surface of the membrane is therefore attached, and is applied upon a layer of areolar texture, interspersed with a more or less rich net-work of capillary vessels; while the other surface is free, and it is only on it that the developed or secondary cells of its germinal spots are attached. These secondary cells are at first contained between the two layers of the membrane, these layers being the opposite walls of each of its component cells. When fully developed, the secondary cells carry forward the anterior layer which is always the thinnest, leaving the nuclei or germinal centres in the substance of the posterior layer, in close contact with the blood-vessels. To show the peculiarities of the primary membrane, it may be observed that it constitutes the outer layer of the true skin; it lines all the cavities formed by mucous membranes, and is prolonged into all the ducts, and ultimate follicles and tubuli of the glands connected with them; it likewise forms the innermost layer of the serous and synovial membranes, and lines the blood-vessels and lymphatics, forming the sole constituent of the walls of their minute divisions. The primary membrane must be regarded as a trentalent structure; furnishing the germ of all the cells which are developed on its surface, as well as the nutritive which they require for their support, its free surface must be continuous undergoing disintegration, and must be as regularly renewed at the side in connexion with the blood-vessels. Fig. 2.

We now proceed to notice the history and functions of isolated animal cells. It is only during the last three or four years that any correct ideas have been maintained regarding the importance of simple isolated cells in the animal economy; each of these cells grows and lives independently of the others, deriving its support from the general nutrient fluid of the part in which it exists.

The animal cell in its simplest form originates from a reproductive granule, previously formed by some other cell; this granule attracts to itself, and assimilates and organizes the particles of nutrient fluid in its neighbourhood, converts some of them into the substance of the cell-wall, whilst it draws others into the cavity of the cell; in this manner the cell gradually increases in size, and whilst it is itself approaching the term of its life, it usually makes preparation for its renewal by the development of reproductive granules in its interior, which may become the germ of new cells when set free from the cavity of the parent. This mode of production and growth is almost identical with that occurring in the vegetable cell; there is however an important difference in their power of producing new active compounds from inorganic matters; whilst the former has no productive power of this nature, but can merely transform one set of compounds into other, so that the formations of simple isolated animal cells are afforded by the corpuscles of blood, lymph, and chyle. There is a certain uniformity in their general character. They are only found in albuminous fluids, and they do not vary very much in size, averaging about the 8000th of an inch in diameter. They are known as lymph or chyle corpuscles, or as the white corpuscles of the blood. These white corpuscles have only of late years attracted much attention, though they had been described as far back as the time of Hewson. In man and the mammalia they are often larger than the red corpuscles; they may be recognised by their granular appearance, their peculiar contour, and their regular shading of their figure. (Fig. 3, parts 4 and 5.) They are also to be distinguished from the red corpuscles by their different actions towards chemical re-agents; they are not attacked by water, but remain in it for a long time without apparent change; they are not rendered transparent, and dissolved by acetic acid; they only become more decidedly granular under its action, and a kind of nucleus is developed in their centre. As they are in all respects similar to those of lymph and chyle, and as they contain the same chemical relations, they have been regarded by many as the corpuscles of the lymph mingled with the blood, and have hence been termed lymph corpuscles (Hewson, Müller); others have yet considered them as glories of the minute blood-corpuscles (Webber); and others again as blood-corpuscles in progress of solution or disintegration. They may be seen in the capillary system of living animals (in transparent structures, as for instance in the frog's foot) swimming with the ordinary blood-corpuscles, but not so much moving rapidly in the great cur.
rent of the blood, as progressing in close contact with the walls of the vessels. They are soft and elastic, like the ordinary corporulae, and seem to stick to each other. The exact functions of these corporulae are still unknown, but there are many facts which seem to indicate that there is a decided relation between them and between the nutritive or organic life of the tissues.

**Fig. 3.**

1. Red corporulae of human blood, exhibiting their flattened surfaces
2. Red corporulae of frog's blood
3. Corporulae of horse's blood
4. Red corporulae of reindeer's blood
5. The same, enlarged by the illumination of a microscope.

On examining a drop of blood under the microscope, we find, in addition to these cells, which are comparatively rare, an immense number of what are termed red corporulae, but which usually present a yellow appearance. These red corporulae have been already noticed in the article Blood, P. C. C. The following are the most important additions made to our knowledge of them since the publication of that article. The blood of numerous animals has been submitted to microscopic examination by Nasse, Wagner, Gulliver, and other observers. In the article Blood it is stated that the red particles of the blood have a circular form in all animals constituting the class mammalia. A remarkable exception to this rule has been shown by Mann to occur in the corporulae of the camel tribe. The mean long diameter of the blood-corporulae of the dromedary is found to be the 226th of an inch, while the mean short diameter was only the 561st of the same standard. In the paco (Auchenia paco) and gusnaco (Auchenia glama) the blood-corporulae scarcely differed in form and size from those of other mammalia, whilst those of the Napa musk-deer were more than half the size of the smallest that have been observed in birds or reptiles.

The difference of size in the corporulae of different mammalia is also worthy of notice. The average diameter of the human of man, according to Mr. Gulliver, is the 339th of a inch, but the average diameter of those of the elephant, according to the same observer, is as much as the 274th of an inch (which were the largest he observed amongst the mammals), whilst those of the Napa musk-deer were more than the 12,525th, and some were as small as the 60,000th of an inch in diameter. There is also an exception to the general statement that the corpuscles of fishes are oval; in one class, namely the Cyecloptomi, or lamprey tribe, they are circular. Neither is the statement now correct that the corpuscles of the skate are the largest known; those of certain reptiles, as for instance the iguana and the crocodile, are considerably larger, and are even visible to the naked eye as very minute specks.

There can be no doubt that the red corpuscles go through the same course as other cells. We have undoubted evidence of their rapid regeneration in cases where much blood has been lost, and of the peculiar power which chalybate medicines have in forwarding their production. The precise method in which they are developed is however not exactly known.

With respect to the chemical composition of the blood-corporulae, we have already stated that the globulin of which the walls are formed seems undoubtedly to be a protein compound. The same is the case with the pigment which received the name of haematin, and is contained in the vesicles of globulin. It has been generally assumed that this substance exists in two distinct states in arterial and venous blood, leaving in the former and excesses of oxygen; and an excess of carbon or carbonic acid. Muller has however shown that its elementary composition is the same whether obtained from arterial or venous blood, and that it may be represented by the formula O₂₂ N₂₂. It is, however, certain that venous blood contains a compound of iron, and no other constituent of the body contains iron. Whatever change the other constituents of the blood undergo in the lungs, this metal is certain, that the globules of venous blood experience a change discolouration, and that this change depends on the action of oxygen. Now we observe that the globules of arterial blood retain their colour in the larger vessels, and lose it only during the passage through the capillaries. All those constituents of venous blood which are capable of combining with oxygen, take up a corresponding quantity of it in the lungs. Experiments made with arterial serum have shown, that when in contact with oxygen it does not diminish the volume of that gas. Venous blood in contact with oxygen is reddened, while oxygen is absorbed, and a corresponding quantity of carbonic acid is formed. It is evident that the change of colour in the venous globules depends on the combination of some one of these elements with oxygen; and that this absorption of oxygen is attended with the separation of a certain quantity of carbonic acid gas. This carbonic acid is decomposed from plasma by the acid of the serum does not possess the property, when in contact with oxygen, of giving off carbonic acid. On the contrary, when separated from the globules, it absorbs from half its volume of oxygen, and becomes equal volume of carbonic gas; and this free carbonic acid is not saturated with that gas. Arterial blood, when drawn from the body, is soon altered; its florid colour becomes dark red. The florid blood, which owes its colour to the globules, becomes dark by the action of carbonic acid, and this change of colour affects the globules, for florid blood absorbs a number of gases which do not dissolve in the fluid part of the blood when separated from the globules. It is evident therefore that the globules have the power of combining with carbonic acid. The globules of the blood change their colour in different gases; and this change may be owing either to a combination or to a decomposition. Sulphured hydrogen turns them blackish green and finally black; and the carbonic acid cannot be restored in this case, be restored by contact with oxygen. Here a decomposition has obviously taken place. The globules darkened by carbonic acid become again florid in oxygen, with the decomposition of carbonic acid. The same thing takes place in nitrous oxide. It is clear that they have undergone no decomposition, and consequently they possess the power of combining with gases, and the carbonic acid of the plasma, as in this case, be restored by contact with oxygen. Here a decomposition has obviously taken place. The globules darkened by carbonic acid become again florid in oxygen, with the decomposition of carbonic acid. The same thing takes place in nitrous oxide. It is clear that they have undergone no decomposition, and consequently they possess the power of combining with gases, and the carbonic acid of the plasma, as in this case, be restored by contact with oxygen. Here a decomposition has obviously taken place. The globules darkened by carbonic acid become again florid in oxygen, with the decomposition of carbonic acid. The same thing takes place in nitrous oxide. It is clear that they have undergone no decomposition, and consequently they possess the power of combining with gases, and the carbonic acid of the plasma, as in this case, be restored by contact with oxygen. Here a decomposition has obviously taken place.
TIS 642

TIS the globules take no share in the process of nutrition, it cannot be doubted that they play a part in the process of respiration. The compound of iron in the globules has the character of an oxidized compound; for it is decomposed by sulphuretted hydrogen, exactly in the same way as the oxides or other analogous compounds of iron. By means of diluted mineral acids, peroxide (sesqui-oxide) of iron may be extracted, at the ordinary temperature, from the fresh or dried red colouring matter of the blood. The characters of the compound of iron are such as to make it a part of the respiratory process. No other metal can be compared with iron for the remarkable properties of its compounds. The compounds of protoproteic acid possess the peculiar properties of the other oxidized compounds of iron; while the compounds of peroxide of iron, under other circumstances, give us oxygen with the utmost facility. Hydrated peroxide of iron, in contact with organic matters destitute of sulphur, is converted into carbones of the protoproteic acid. Carbonate of protoproteic acid, in contact with water and oxygen, is decomposed; all the carbonic acid is given off, and by absorption of carbonic acid it passes into the hydrated peroxide, which may again be converted into a compound of the protoproteic acid. Not only the oxides of iron, but also the cyanides of that metal, exhibit similar properties. Prussian blue contains iron in combination with all the organic matters of the body. The iron is in combination with both hydrocarbons and oxygen (water), carbon and nitrogen (cyanogen). When it is exposed to light, cyanogen is given off, and it becomes white; in the dark it attracts oxygen, and recovers its bluish color. The characters that the one exhibits when it is exposed to light, and the other when it is exposed to darkness, agree with our opinion that the globules of arterial blood contain a compound of iron saturated with oxygen, which in the living blood loses its oxygen during its passage through the capillaries. When the temperature is raised, it is converted into the white state, and begins to undergo decomposition. The compound, rich in oxygen, passes therefore, by the loss of oxygen, into one far less charged with that element. One of the products of oxidation formed in this process is carbonic acid. The compound of iron in the venous blood possesses the property of combining with carbonic acid; and it is obvious that the globules of the arterial blood, after losing a part of their oxygen, were involved in the reaction with carbonic acid, and obtained what we call the pneumonia. When they reach the lungs, they will again take up the oxygen they have lost; for every volume of oxygen absorbed, a corresponding volume of carbonic acid will be separated; they will return to their former state, that is, they will again acquire the power of giving off oxygen. For every volume of oxygen which the globules can give off, there will be formed (as carbonate contains its own volume of oxygen without condensation) neither more nor less than an equal volume of carbonic acid. For every volume of oxygen which the globules are capable of absorbing, no more carbonic acid can possibly be separated than that volume of oxygen can generate. When the degree of oxidation is the same, the amount of oxygen passes into the hydrated peroxide, there are given off, for every volume of oxygen necessary to the change from protoproteic iron to the oxidized, four volumes of carbonic acid gas. But from the one volume of oxygen, and only one volume of carbonic acid gas can be produced. And the absorption of one volume of oxygen can only cause directly the separation of an equal volume of carbonic acid; consequently the substance or compound which has lost its oxygen during the passage of arterial into venous blood, must have been capable of absorbing or combining with carbonic acid; and we find, in point of fact, that the living blood is never, in any state, saturated with carbonic acid; that it is capable of taking up an additional quantity without any apparent disturbance of the functions of the globules. Thus, for instance, after drinking effervescing wines, beer, or mineral waters, more carbonic acid must necessarily be expired than at other times. In all cases where the oxygen of the arterial globules has been partly extended otherwise than in the formation of carbonic acid, the amount of this latter gas will be proportionate exactly to that which has been formed; less however will be given out after the use of fat and of still-wines than after champagne. According to the views now developed, the globules of arterial blood in the fresh or dried state, as well as in the fluid under the capillaries, and in the living body, are continually oxygenating the constituents of the body. A small portion of this oxygen serves to produce the change of matter, and determines the separation of living parts, and their conversion into lifeless corpuscles, which are the final products of the formation of the body. The greater part, however, of the oxygen is employed in converting into oxidized compounds the newly-formed substances which no longer form part of the living tissue. In their return towards the heart, the globules which have lost their oxygen combine with carbonic acid, producing venous blood; and when they reach the lungs, an exchange takes place between this carbonic acid and the oxygen of the atmosphere. The organic compound of iron, which exists in venous blood, is converted in the lungs the oxygen it has lost, and in consequence of this absorption of oxygen the carbonic acid in combination with it is separated.

Mulder is strongly opposed to this theory; he denies that the iron takes any share in the respiratory process; and he refers the process entirely to the oxidation of the protein-compounds. He alleges the following grounds against the probability of the correctness of Liebig's views on this subject.

1. The iron is intimately connected with the other elements of hematin, that it cannot be removed even by long digestion of this constituent in dilute hydrochloric or sulphuric acid. If these re-agents cannot effect its oxidation, it is highly improbable that it should be oxidized in the lungs.

2. If, as Liebig asserts, peroxide of iron exists in arterial blood, the oxygen of this would be capable of removing any dilute acid would be capable of removing it. But this is not the case. Hematin, properly prepared, may be digested with dilute hydrochloric or sulphuric acid for many days without any perceptible change; but, if the hematin is not treated in this manner Mulder obtained by combustion 9·49 per cent. of peroxide of iron, which is the constant quantity always left after the combustion of well-prepared hematin.

3. The probability that the iron exists in a metallic state is strongly supported by the observation that hydrogen is evolved when a clot of blood is digested in sulphuric acid, and water is not absorbed. Mulder suggests that it occurs as an integral constituent of hematin in just the same manner that iodine occurs in sponge, sulphur in cynsin, or arsenic in the cacodyl series.

4. The fact of hematin in the whole mass of the blood is far too inconsiderable to carry a due supply of oxygen to the whole system.

Having thus shown the principal objections to which Liebig's celebrated theory is open, we shall endeavour briefly to explain the rival theory of Mulder. We have at an early part of this article shown that the protein-compounds are capable of undergoing oxidation when in contact with the oxygen of the air. When a protein-compound becomes oxidized, it assumes a plastic character, that is to say, it has a tendency to become solid and to adhere to solid substances. Now we have already mentioned that the blood-corpuscles are principally composed of a protein, the phosphoglycin, or globulin. When a respiration is performed, the exterior layer of such of the corpuscles as are exposed in the lungs to the action of the oxygen of the air is converted into a white layer, or globulin; it becomes whitish and less transparent. This is the same as in the blood-corpuscles of the capillary system, where the whole external layer is employed in the change of material of the body, and is in that way consumed. Having lost this white layer, they again become transparent. The dark-colouring substance in the corpuscles of arterial blood, shining through a white layer, must necessarily appear of a bright red tint, as may be shown by pouring dark red blood into a vessel of milky glass.

The preceding observations have been made with the view of showing the utility of these isolated animal cells—the blood-corpuscles—and their reproductive process. We shall revert again to the distinctions between the characters of venous and arterial corpuscles in our remarks on the colour of the blood.

In our remarks on various tissues we shall often again have occasion to notice these peculiarities. We shall give another illustration of their utility, namely, their importance in the process of nutrition. Mr. Goodall has recently shown that there is a continual development of cells at the extremity of each reagent, and that the agents by which the secretion of the nutritive fluid is accomplished, and by which it undergoes its first preparation for the purposes it is subsequently to fulfil. The process takes place as follows: the reagents enter into contact with the blood-corpuscles, and the observations in his own words, omitting those portions which do not bear specially on the point.

As the chyle begins to pass along the small intestine,
increased quantity of blood circulates in the capillaries of the gut. In consequence of this increased flow of blood, or from some other cause, the pigments are distributed, the internal surface of the gut throws off its epithelium, which is intermixed with the chyme in the cavity of the gut. The cast-off epithelium is of two kinds,—that which covers the villi, and that which is on the mesentery. Each of these forms, may be termed a protective epithelium; and that which lines the follicles, and is endowed with secreting functions. The same action then, which in removing the protective epithelia from the villi prepares the matter for the function of absorption, throws out the secreting epithelia from the follicles, and thus conduces towards the performance of the function of these follicles. This villi, being now devoid of blood, erected, and naked, are covered or coated by the white-grey matter already described. This matter consists of chyme, of cast-off epithelia of the villi, and of the secreting epithelia of the follicles. The function of the villi now commences. The minute vessels which are interspersed among the terminal loops of the lacteals of the villus, increase in size by drawing materials from the blood through the coats of the capillary vessels, which ramify at this spot in great abundance. While this increase in their capacity is in progress, the growing vesicles are continually exerting their absorbing function, and draw into their cavities that portion of the chyme in the gut necessary to supply materials for the chyle. When the vessels respectively attain in succession their specific size, they burst or dissolve, their contents being cast into the texture of the villus, as in the case of any other species of interstitial cell. The debris, and the contents of the dissolved chyle cells, as well as the other matters which have already subserved the nutrition of the villus, pass into the looped network of lacteals, which, like other lymphatics, are continually employed in this peculiar function. As long as the cavity of the gut contains chyme, the vesicles of the terminal extremity of the villi continue to develop, to absorb chyle, and to burst, and their remains and contents to be removed along the lacteals. When the gut contains no more chyme, the flow of blood to the mucous membrane diminishes, the development of new vesicles ceases, the lacteals empty themselves, and the villi become flaccid. The function of the villi now ceases till they are again roused into action by another flow of chyme along the gut. During the intervals of absorption, it becomes necessary to protect the villi from the matters contained in the bowel. They had thrown off their protective epithelium when required to perform their functions, just as the stomach had done to afford gastric juice, and the intestinal follicles to supply their peculiar secretions. In the intervals of digestion the epithelium is rapidly reproduced.\textbf{Fig. 4.}

![Extemity of a villus with its absorbent vessels distended with chyle, and the vessels in its coats. Very magnified.](image)

The researches of Mr. Goodir have likewise thrown much light on the general process of secretion. He shows, by an admirably selected series of observations (chiefly on the lower animals), that secretion is a function of the nucleated cell. If a whole organ, especially a liver, or a secreting portion of the internal surface of the ink-bag of *Loligo vulgaris* (Lamarck) be carefully freed from adhering secretion by washing, it will be found to consist almost entirely of nucleated cells, of a dark brown colour. If the organ be dissected out from the nutritive medium, the secreting matter which does not exist in it. The discovery of the secreting agency of the primitive cell does not remove the principal mystery in which this function has always been involved. One cell secretes bile, another cell milk; yet one cell does not differ more in structure from the other, than the lining membrane of the duct of one gland from the lining membrane of the duct of another. The general fact however, that the primitive cell is the ultimate secreting structure, is of great value in the biochemical science inasmuch as it connects secretion with growth, as phenomena regulated by the same laws. The force, of whatever kind it may be, which enables one primary formative cell to produce nerve and muscle, by the formation of itself of the common materials of nutrition, is identical with
that force which enables one primary secreting cell to distend itself with bile and another with milk.

Instead of growth being a species of imbibing force, and secretion on the contrary a repulsive, the one centripetal, the other centrifugal, they are both centripetal. Even in those cases where the two processes, growth and secretion, do not differ. The primary formative cell, after becoming distended with its peculiar nutritive matter, in some instances changes its form according to certain laws; and then, after a longer or shorter period, dissolves and disappears in the intercellular space in which it is situated; its materials passing into the circulating system if it be an internal cell, and being blown off if it be an external cell. The primary secreting cell, again, after distension with its secretion, does not change its form so much as certain of the formative cells, but the subsequent stages are identical with those of the latter. It bursts or dissolves, and throws out its contents either into ducts or gland-cavities.

The general fact of every secretion being formed within cells, explains a difficulty which has hitherto puzzled physiologists, namely, why a secretion should only be poured out on the free surface of a gland-duct, or secreting membrane. We have attempted to illustrate Mr. Goodair's views by the accompanying figure.

Fig. 5.

1. Cells from the kidney of Rana esculenta; the contained secretion is dead-white and presents a characteristic appearance.
2. Cells from the liver ofasts (Leptosynapsis).
3. Cells from the rectum of a bat (Rhinolophus ferrumequinum). In this instance the bile is contained in the cavities of the secondary cells, which constitute the nucleus of the primary cell.
4. Cells from the mammae of a bitch. In addition to their nuclei these cells contain milk-globules.

1. Persistent tissues. We now proceed to the histological and chemical investigation of the most important constituents of the human organism.

1. Adipose tissue is usually associated with areolar tissue (which see), the two being generally known collectively as cellular tissue. It must be distinguished from fat, the former being a membrane of extreme tenuity in the form of closed cells or vesicles, while the latter is the material contained within them. The membrane of the adipose vesicle does not exceed the 20,000th of an inch in thickness, and is quite transparent; it is moistened by watery fluid, for which it has a greater attraction than for the fat it contains. Each vesicle is a perfect little organ, varying, when fully developed, from the 300th to the 800th of a line; minute capillaries may be observed on their external surface. When fat-vesicles are deposited together in large numbers, as is usually the case, they assume a more or less regular polyhedral form from their mutual pressure.

Fig. 6.

When the first traces of fat appear is not accurately known. In a well-formed five-months human fetus Valentin found in the subcutaneous cellular tissue of the sole of the foot not merely fat-cells, such as occur in adults, varying from the ordinary size to the 125th or 100th of a line, within and around which were numerous small vessels (Fig. 6, a), but other forms which threw more light on their structure and development. In some the surrounding cell-membrane was much more distinct than as it occurs in adults (b). In others there appeared to be a deposition of fat, not occupying the whole space of the cell (g); the remainder of the cell having often a striped or streaky appearance, and forming a lateral projection; this is seen in c, and in a more marked degree in d and e. In other cells there were observed to be two vesicles, separated by a septum, against which they were partially flattened by pressure (g), or merely separated by a constriction in the external walls, as in f. This form leads us to conclude that fat-cells increase by division. For the chemistry of this constituent we must refer to the article Fat, P. C., and to an early part of the present article. It is sufficient here to remark that the fat-vesicle of the human subject contains margarin, a solid, and olein, a fluid fat. These sometimes separate spontaneously, presenting a very beautiful microscopic appearance. The margarin collects in a spot on the inner surface of the cell-membrane, and presents the appearance of a small star, whilst the olein occupies the remainder of the vesicle, unless when the quantity of fat in it is rather smaller than usual, in which case we may observe a little aqueous fluid between the olein and the cell-membrane. We have attempted to depict this separation in h.

2. Pigment.—In certain parts of the animal organism we meet with definite and well-marked colorations, not dependent on any peculiar arrangement of fibres, etc., but on the presence of pigment-granules of various colours. These granules are usually inclosed in cells, termed pigment-cells. In all races of men we find a most remarkable development of these cells on the inner surface of the choroid coat of the eye, where they form several layers known as the Pigmentum posterius. They are probably always mingled with the epithelial cells, giving rise in the dark races to the deep colour of the skin and presenting themselves in the white races in the form of flecks, the areola round the nail, &c. The pigment-cells are usually fat and laterally compressed into the polygonal form. The granules in their interior are extremely minute, retain their dark colour under high magnifying powers, but exhibit various forms. In the choroid membrane of the human eye their form is very regular; in the adult no nucleus can be seen, a structure which is obvious in corresponding cells from the fetus. The pigment-cells have not always a simple rounded or polygonal form; they sometimes present remarkable stellate prolongations and other singular shapes, which we have attempted to depict in Fig. 9, representing pigment-cells from a frog. a, b, c, d, e, and g, Fig. 9, are representations of various pigment-cells from its choroid coat, while f is intended to exhibit the stellate shape in which these cells occur on the skin of that animal. The nucleaus

Fig. 7.

Fig. 8.

Similar cells from a fetus at the third month.

Fig. 9.
is sufficiently obvious in one of the cells in a, in c, d, e, and f. Little is known of the chemistry of the animal pigments. Scherer has made three analyses of the black pigment from the eye of the ox, from which he concludes that it consists of Carbon 58.294, Hydrogen 6.918, Nitrogen 13.768, Oxygen 22.880.

From these analyses it appears probable that the black pigment contains a larger amount of carbon than any other constituent of the animal body.

3. Horny tissues.—Under this general name are included not only true horns, but feathers, hairs, cuticle, and the various forms of epithelium and the stratum corneum. We shall confine our observations to the microscopic characters of epithelium and hair, and then briefly advert to the general chemical characters of the class.

The epithelium may be regarded as a delicate cuticle covering the free internal surfaces of the body, just as the epidermis (to which it is closely allied) invests the external surface. Some of the uses of the epithelial cells have been already noticed in our remarks on isolated cells, in addition to their obvious use in protecting the surfaces on which they are placed. This structure was first investigated by Henle (in Müller's Archiv, 1838), and has been since carefully examined by Bowman (art. 'Mucous Membranes,' in Todd's 'Cyclopedia of Anatomy and Physiology,' 1842), Goodair, and others. From the forms presented by the epithelial particles they have received different names. Henle divided them into pavement or tissued epidermis, cylinder epithelium, and ciliated epithelium, and although they frequently run in one another, yet on the whole these distinctive terms are serviceable.

Fig. 10.

The pavement epithelium consists of broad flattened particles, or scales, having an angular outline and a nucleus; these scales form layers of extremely variable thickness. Fig. 10, A, shows very clearly how they are superimposed over one another, forming an efflorescent protection to the basement membrane beneath them. As a general rule the nucleus is large in proportion to the youth of the cell. In this figure we have attempted to exhibit these cells in two stages, a recent and a mature stage. In the young cells marked a the nucleus is relatively much larger than in b. This figure is intended to represent the epithelial scales of the frog: the larger cells, b, lying upon the younger and smaller cells, a.

This form occurs on all synovial and serous membranes, and on most of the mucous membranes.

In the cylindrical epithelium the particles have the shape of small rods disposed endways on the basement membrane in a single layer. In consequence of their mutual compression they usually assume a prismatic rather than a cylindrical form, and hence Bowman applies the term prismatic to this form of epithelium. This form is perhaps best seen on the villi of the small intestine, and on the conjunctival surface of the cornea of the eye. We have attempted to depict the latter in Fig. 10, B.

The ciliated epithelium is little more than cylinder epithelium, but instead of these are scattered numerous cilia or delicate filaments, these are observed in actual motion (Fig. 10, C). When in motion each filament appears to bend from its root to its point, returning again to its original state like corn moved by the wind. The motion of the cilia is independent of the will of the animal, but seems even to be independent of the life of the rest of the body; it has been seen after the death of the animal, and proceeding with perfect regularity in parts separated from the body. Dr. Carpenter states that ciliary movement has been observed fifteen days after death in the body of a tortoise. The motion may be readily observed in the oyster or mussel. In the human subject this form of epithelium exists in the sinuses, except with various offsets, as the nasal cavities, maxillary and ethmoid tubes, lacrimal ducts, &c., and in the upper part of the vagina, the uterus, and the fallopian tubes. Its purpose is evidently to propel fluids over the surfaces on which it occurs.

Hair. The shaft of the hair is that portion which is fully formed and projects beyond the surface. On examination we find it lodged in a follicular involution of the basement membrane (Fig. 11, a), which usually passes through the cutis into the subcutaneous muscular tissue. This cuticle and the cuticle of the hair is a bony-like substance formed by the direct action of the hair on its own substance. The hair grows from the bottom of the follicle, and the cells of the deepest stratum, resting on the basement-membrane, are very similar to those which in other parts are transformed into scales of cuticle. A gradual enlargement occurs in these cells as they form the soft bulk of the hair, which indeed gives it its size to this circumstance. If the hair is to be coloured, the pigment-grains are also here developed, for the most part in scattered cells, which may send out radiating processes; at other times, in a diffused manner around the nucleus of the cells generally. It frequently happens that the cells in the axis of the bulb become loaded with pigment at one period, and not at another; so that, as they pass upwards in the shaft, a dark central tract is produced of greater or less length, often only in irregular patches, and the hair appears here and there to be tubular. e. The shaft is much narrower than the bulb, and is produced by the rather abrupt condensation and elongation into hard fibres of the cells, both of which contain pigment and those which do not. The granules of pigment assume a linear arrangement between the fibres, which are firmly united into a solid rod by a material similar, it may be supposed, to that which cements the scales of the cuticle.

The human hair has a proper bark, or cortex, formed in the following way:—A single layer of the cells immediately surrounding these about to form the fibrous tissue of the shaft are seen near the bottom of the follicle to assume an imbricated arrangement (Fig. 11, c), and gradually to mount on the hair, becoming more compressed against it in their ascent, until they form upon its surface a thin transparent colourless film, in which the outline of the delicate cells is still exhibited by elegant and exceedingly fine sinuous lines.

Fig. 11.
The fibrous interior and this peculiar cortex together compose the shaft of the hair. By the continuance of the outer portion of the shaft from the follicle, fragments of the cuticular lining of the latter are apt to be drawn up upon the hair, sided probably in this by the imbrication of its surface, and are often found clinging around, is for some way, but they are not to be regarded as any part of the hair itself. From the preceding description it will be evident that the fibrous part of the hair is a peculiar development of the cuticular cells resting on the bottom of the follicle, that the imbricated cortex is formed by a single series differently developed at the circumference of these, and that beyond this series comes the cuticular lining of the follicle, so that the hair is neither covered nor underlaid by cuticle, but it is in fact the moulded outside of the bottom of the follicle.

Fig. 12.

The figure and the description of the structure are copied from Todd and Bowman's *Physiological Anatomy and Physiology of Man*, vol. ii. p. 418.

The chemistry of horny tissues has been specially investigated by Scherer and Van Laer. The following analyses of various tissues of this class have been analyzed by the former chemist (Liebig and Wöhler's *Annalen*, vol. xi. p. 33):

From the analyses of Van Laer it appears that the average amount of sulphur in human hair is 5 per cent. From a series of well-defined experiments he concludes that "the hair consists essentially of:

1. A connecting medium consisting of a tissue yielding gelatin, and represented by the formula C H N O S.

2. Of bisulphate of protein, C H N O S.

The large amount of sulphur is the cause of its colour being affected by various metallic salts. As there is no constant difference to be observed in the results obtained by the analysis of hair of various tints, it is to be presumed that the colour is dependent on peculiar arrangements of the ultimate particles." Hair further contains about 0.4 per cent. of persulphate of iron, which is supposed by Van Laer to be chemically combined with the protein.

4. Fibrous and Arterial tissues.—Fibrous tissue is now usually considered under two heads, namely as the white and the yellow fibrous tissue.

White fibrous tissue occurs in ligaments, tendons, and membranes requiring great strength. On carefully dissecting away the areola; tissue with which it is associated, it seems, when examined under the microscope, to consist of extremely delicate fibrillae running parallel to one another, and taking an undulating course. There is however reason to believe it does not in reality consist of a bundle of fibrillae, but that it is simply a mass with longitudinal parallel streaks, and which has a tendency to split up in a longitudinal direction (Fig. 14, a).

Yellow fibrous tissue differs in many essential points from the preceding form. It is remarkably elastic, is of yellow colour, and is arranged in bundles or fibres, invested by a thin sheath of areolar tissue. In man we find it extended between the laminae of the vertebrae, in several other ligaments, and in the transversalis fascia of the abdomen. It forms the ligamentum nuchae of animals. Examined under the microscope it is seen to consist of fibres varying in diameter from the 5000th to the 10,000th of an inch. They bifurcate or even divide into three, and freely anastomose with each other.

Fig. 13.

The two elements of Arterial Tissue in their natural relations to one another, a. the white fibrous element, with cell-nuclei, b. sprawling visible in the white fibrous tissue, c. fibrille of the yellow element, far finer than the rest, but having a similar minute diameter, d. nucleated cell-nuclei, often seen apparently loose.
These two tissues may be most easily discriminated by the addition of a drop of dilute acetic acid, which at once swells up the former and renders it transparent, whilst it produces no change in the latter. It thus brings into view corpuscles of an oval shape, which are probably the nuclei of the cells from which the bands have been originally produced. Oval corpuscles (Fig. 14, d), either altogether isolated or having very delicate prolongations with the adjacent threads, are sometimes noticed. They seem to be either advancing or receding stages of the tissue.

In Fig. 15, which represents the aracidal tissue from beneath the skin of a five-months foetus, we can perceive the cells elongating into fibres.

In a chemical point of view the leading difference between the white and yellow tissues is, that the former is acted on by acetic acid in the manner already described, and yields a considerable amount of gelatin in boiling; whilst the latter resists the action of acetic acid, and yields little or no gelatin.

5. Nervous Tissue.—In a microscopic point of view nervous tissue may be separated into two elements, the vesicular and the fibrous. The vesicular nervous matter is grey or cinctorous in colour and granular in its texture, containing nuclei in its vesicles, and being largely supplied with blood. The fibrous nervous matter is, on the other hand, usually white, and composed of tubular fibres, although in some parts it is grey, and consists of solid fibres; it is also less vascular than the preceding. The former is more immediately associated with the mind, and is the originating seat of the force manifested in nervous actions; whilst the latter is simply the propagator of impressions made on it. The union of these two kinds of matter constitutes a nervous centre, and the threads of fibrous matter which pass to or from it are called nerves. The smaller nervous centres are termed ganglia; the larger ones are the brain and spinal cord.

Two species of primitive fibre have been observed by microscopists in the fibrous matter; they have been named the tubular fibre, or the nerva-tube, and the gelatinous fibre; the latter is comparatively rare, and is seldom found except in the sympathetic system.

The tubular fibre is a tube composed externally of a fine transparent homogeneous membrane, very much resembling the sarcolemma of muscle, which will be presently noticed. Nucleated cells may however be occasionally seen in it, as in Fig. 16, which represents a portion of the sciatic nerve of a frog. This may be termed the tubular membrane of nerve.

The contents of this tube consist of a soft, semi-fluid, whitish, pulpy substance, which is readily pressed out of its cut extremity. This is termed by Schwann the white substance, since the white colour of the nerve-tubes is dependent on it. Within this and occupying the centre of the tube is a transparent, somewhat flattened band, which is extremely delicate, and in which it seems impossible to recognise any more definite structure. Hence the tubular fibre consists of three distinct elements.

The tubes when quite fresh are perfectly cylindrical; but very slight pressure or almost any disturbing influence gives rise to swellings or enlargements in the course of the fibre, causing it to assume a varicose appearance. Two conditions seem to favour the production of this change: namely, a feeble power of resistance in the tubular membrane, and a semi-fluid state of the contained nervous pulp. In the nerves of the special senses the tubes are very delicate in structure, and are very apt to exhibit this change of form, and in the brain and spinal cord they present the same tendency. We mention this appearance because Ehrenberg formerly observed that these varicosities were natural and existed during life, and that they furnished a valuable morphological character of the nerves of the spinal sense and the cerebro-spinal centres.

In point of size the nerve-tubes present considerable variety even in the same trunk; and in the different classes of animals the differences are well marked.

In man and other mammals they vary from the 1024th to the 6500th of an inch in birds, from the 2000th to the 3000th of an inch; in reptiles—from the frog—from the 1296th to the 2280th of an inch; in fish—in the eel—they are the 1043rd of an inch, and in the optic nerve of the cod-fish they are the 650th of an inch. These primitive tubules present no subdivision or branching. Whatever be the connexion which each primitive tubule forms with the nervous centre and with the textures to which it is distributed, it passes from one point to the other without any change, save perhaps in size, and without any communication with neighbouring tubules, beyond possibly investment by a common sheath.

The gelatinous nerve-fibre is a term applied by Hesse to certain fibres occurring principally in the sympathetic nerve, and which may be regarded as its distinctive element. They are flattened, soft, and homogeneous in their appearance, bearing a considerable resemblance to unstriped muscular fibres; and like them, they contain numerous cell-nuclei, which are frequently arranged in a tolerably regular manner. These nuclei are brought in view by acetic acid, which dissolves the rest of the fibre, leaving them unchanged. These fibres contain nothing analogous to the white substance of Schwann, and hence are devoid of that whiteness which characterises tubular fibre. It seems that the grey colour of certain nerves depends chiefly on the presence of a large proportion of the gelatinous fibres. Hence they are sometimes termed grey fibres. They are usually smaller than the tubular fibres, their diameter ranging between the 6000th and the 4000th of an inch. Both classes of fibres appear to run continuously from one extremity of the nervous cord to the other, without anything like union or anastomosis; each ultimate fibre probably having its distinct office which it cannot share with the others.

We now proceed to the consideration of the vesicular nervous matter, which in its normal form may be regarded as glabular (Fig. 16, A, c, and B, e). This form is however liable to great variation, and from the compression to which these nerve or ganglion-glubules, as they are termed, are exposed, they may become oval or polygonal, or they may extend...
into one or more long processes, giving them a caduceus or star-like aspect.

The wall of each vesicle consists of an exceedingly delicate mass, containing a soft but tenacious finely granular mass. The nucleus is generally eccentric, much smaller than the containing vesicle and adherent to some part of its interior. Its structure is apparently the same as that of the outer vesicle. The nucleus is a minute, remarkably clear, and brilliant body, also vesicular, enclosed within the nucleus. The processes to which we have alluded contain the same granular matter as the cells, with which they seem to be continuous. They are extremely delicate, and generally break off close to the nucleus; sometimes however they may be traced to a considerable distance, and will be found to divide into two or three branches, which undergo further subdivision. It is most probable that they either serve to connect distant vesicles or that they become continuous with the flattened bands occurring in the centre of the tubular element. In most situations where vesicular matter is found in the nervous centres, tubular fibres and sometimes both varieties of fibre are also present. We have attempted to depict this union in Fig. 18.

The varying amount of phosphorus has been supposed to stand in some connexion with the mental powers; this view must however at present be deemed merely hypothetical. The nerves according to L'Heritier contain more albumen, less solid and more soft fat, than the brain.

Pacinian Corporules. These bodies, so called from Pacini their discoverer, are found in the human subject in great numbers in connexion with the nerves of the hand and foot, but they also exist sparingly on other spinal nerves and on the pleuraxes of the sympathetic, though never on the nerves of motion. In the mesentery of the cat they may be almost always detected by the naked eye, being pellucid oval grains rather smaller than hemp-seeds.

A gives a correct idea of their relation to the nerves in the palm and sole. In the human subject they vary from the 10th to the 20th of an inch. The structure of these bodies is highly singular. They consist, first, of a series of membranous capsules, from thirty to sixty or more in number, enclosed one within the other; and, secondly, of a single nervous tubular fibre enclosed in the stalk, and advancing to the central capsule, which it traverses from end to end.

The numbers in each instance represent the mean of six animals:—

The Chemistry of Nervous tissue. In the 'Annales de Chimie,' for 1841, there is a memoir by Fresny on this subject. From the fatty matter of the brain, which usually amounts to 5 or 6 per cent., he isolated several secondary compounds; namely, 1. Cerebric acid; a white substance in the form of crystalline grains, abounding in carbon, and containing a minute proportion of phosphorus. 2. Cholesterin; 3. Oleo-phosphoric acid, a peculiar fatty acid containing about 2 per cent. of phosphorus in the form of phosphoric acid; and 4. Traces of olein, margarin, and fatty acids. The following table has been drawn up by L'Heritier from his own researches:—

Pacinian corporules from the mesentery of a cat; intended to show the general construction of these bodies. The stalk and body, the outer and inner capsule, with the central cavity, are seen.

A, Arterial twig, ending in capillaries, which form loops in some of the interior layers of the mesentery; B, penetrates in the central capsule. A, The Sherrin capsule of the stalk, prolonged from the nerve-capsule. B, Nerve tube advancing to the central capsule, there losing its white substance, and stretching along the stalk to the opposite end, where it is fixed by a tabular enlargement. Todd and Bowman.

In the above figure, which exhibits the general structure, the ten or fifteen innermost capsules may be observed to be in contact with one another, while the rest are separated by a clear space containing fluid.

Respecting the function or use of these corporules no satisfactory account has yet been given. Pacini himself inclined to believe that they may be concerned in the phenomena of what is called animal magnetism.

Muscular tissue. There are two forms of muscular fibres, differing extremely in their microscopic characters. The fibres of the voluntary muscles, as well as the fibres of the heart and of some of those in the oesophagus, are striped or striated; while all other muscles, including those of the alimentary canal, the uterus, and bladder, all of which are involuntary, are unstriped or non-striated. [Murray, P. C.]
The elementary fibres of the voluntary muscles are arranged in sets parallel to one another, whilst those of the involuntary muscles usually cross at various angles, and interface, forming membranous organs, enclosing a cavity which their contraction serves to contract.

The striated fibres are usually of about the same length as the muscle to which they belong. In the sartorius they often exceed two feet in length, while in the stapedius (in the middle ear) they are not two lines. They vary in diameter from the 60th to the 1400th of an inch, being largest in crustaceans, fish, and reptiles, where their irritability is most enduring, and smallest in birds, where it is most evanescent. In man their average diameter is the 400th of an inch. The fibre always presents upon and within it longitudinal dark lines, along which it subsequently splits up into fibrillae; but it is by a fracture alone that these fibrillae are obtained; they do not exist as such in the fibre. Sometimes, on the application of violence, cleavage takes place in a different manner, in a plane at right angles to the long axis of the fibre. In this case fibrillae and fibrillae are retained; and the cleavage is just as natural as the former, though less frequent.

Fig. 21.

A. Fragments of elementary fibres, showing a cleavage in opposite directions.

B. Longitudinal cleavage. The longitudinal and transverse lines are both seen. c. Fibrillae separated from one another by violence at the broken end of the fibre, and marked by transverse lines equal in width to those on the fibre. c' represents the appearances commonly presented by the separated single fibrilla (more highly magnified). At c the borders and transverse lines are all perfectly rectilinear, and the included spaces perfectly rectangular. At c' the borders are sawed and the spaces beak-like. When most distinct and definite the fibilla presents the former of these appearances. a. Transverse cleavage. The longitudinal lines are usually visible. a. Incomplete fracture following the opposite surface of a disc, which stretches across the interval and retains the two fragments in connection. The edge and surface of this disc are seen to be minutely granular, the granules corresponding in size to the thickness of the disc, and in lig distance between the joint longitudinal lines. b. Another disc, nearly detached. b'. Detached disc more highly magnified, showing thenumerous elements. bowman in Todd's Cycliographia.

Hence the fibre must be regarded neither as a bundle of fibrillae nor a pile of discs, but as 'a mass in whose structure there is an irritation of the existence of both, and a tendency to cleave in the two directions.' The same particles compose the disc and the fibrilla, and they have received the name of the primitive or sarcomatous elements. The cross stripes of the fibre are formed, according to the views of almost all the best observers of the day, by the apposition, side by side, of the dark points seen on the separated fibrilla. That they are not caused by a structure distinct from the fibrilla, and present only on the surface of the fibre, is evident, according to Todd and Bowman, from the following facts:

1. That a transverse section of a fibre shows it to be solid and not hollow, and that the ends of the fibrilla, as seen on its section, exist throughout its interior, just as on its surface.

Fig. 22.

Transverse section of three elementary fibres of the dried posterior muscle of a teal, treated with weak nitric acid.

2. That fibrilla taken from any part of a fibre are marked with light and dark points, corresponding in distance and force with the transverse stripes of the fibre.

P. C. S., No. 167.

3. That with a high magnifying power applied to a single fibre we may bring all parts of its interior into focus in succession, and perceive throughout the same kinds of stripes.

The Sarcomatous or tubular sheath enclosing the striated fibre, consists of a transparent, very delicate, but tough and elastic membrane, which isolates the fibre from all other tissues. It most commonly has no appearance of structure, but occasionally small corpuscles, the remains of cell-nuclei, are observed in it.

Fig. 23.

If the fibre be immersed in acid, it swells, bursts the sheath, and forms small protrusions or herniae.

The researches of Valentia and Schwann have thrown much light on the development of muscular tissue in the embryo. In its earliest stage, muscle consists of a mass of uninucleated cells which first arrange themselves in a linear series, and then unite to form the elementary fibres.

Fig. 24.

Stages of development of striated muscle fibres.

a. Arrangement of the primitive cells in a linear series.
b. The cells united, the nuclei separated, and some broken up; longitudinal lines becoming apparent. From a fertilised embryo, three inches long.
c. e. Transverse stripes apparent. c. The nuclei are internal and lodged the fibre; in d they are prominent on the surface. From a fertilised embryo, two months old.
d. Transverse stripes fully formed and dark; nuclei disappearing from view. From the human infant at birth.
e. Elementary fibre of a perfect fetus, treated with acid, showing the nuclei a from Schwann. The rest from Bowman.

As the cells unite, a depot of contractile material gradually takes place within them. The deposition assumes a granular form, the granular or sarcomatous elements being of the same size as in the perfect muscle; for this reason the transverse stripes resulting from their apposition are of the same width as in the adult. Muscles grow by an increase, not of the number, but of the bulk of their elementary fibres.

The unstriated or non-striated fibres consist of flattened bands, generally of a pale colour, bulged at intervals by oval or elongated corpuscles. Their texture seems to be homogeneous. By transmitted light they have usually a soft and very finely motled aspect; their ordinary diameter varies from the 3000th to the 2000th of an inch.

Chemical characters of Muscle.—In consequence of the difficulty that exists in separating muscular fibre from aseptic tissue, vessels, and nerves, it is impossible to speak with certainty regarding its behaviour towards re-agents. Playfair and Bockeann have analyzed the dried muscular flesh of the ox, and found it to be identical in its composition with dried fibres. For analyses of the flesh of man and of various animals we refer to Simon's Chemistry, vol. ii. p 422-425.

7. Cartilaginous Tissue.—The simplest form of cartilage consists merely of nucleated cells, and closely resembles the cellular tissue of plants. This kind is found in the rudimentary spinal column of the early embryo; it also exists in the chords dorsals of the cartilaginous fishes. In other kinds of cartilage the cells are embedded in an intercellular substance presenting certain varieties of appearance.
The canals which are everywhere found traversing variously the substance of the bone, and giving passage to the blood-vessels for the nourishment of the tissue, are called Haversian Canals, a name given them in consequence of Clapton Havers having been the first who gave a full account of them. The parietes of these canals have a laminated arrangement. The laminae themselves are numerous and placed concentrically; the internal lamina, that which is in immediate contact with the vessel or vessels, being the most distinctly marked, and each succeeding one having a less distinct outline.

Besides the concentric laminae, there are others which surround the exterior of the bone, and may be known as the superficial lamina. In connection with both the concentric and superficial lamina are a third set, which cannot belong to either of the other orders, but which are placed between them, and form the bond of union between each system.

Much has been lately written on the bone-corpuscles. These are small cells, of oval form, placed between the laminae, and having numerous distinct tubes running from them in almost every direction. They have been sometimes compared to a spider with many legs. The corpuscles, or, as they are occasionally called, the calcigerous cells, have a definite relation to the Haversian canals and to each other.

The Haversian Canals, the osseous laminae, and the bone-corpuscles are therefore the leading points to be mentioned in treating of the structure of the bone. Upon a closer view, however, it will be seen that it is only the lamina which are

Bone; the canals and corpuscles are spaces existing in bone, and are not really necessary to the existence of osseous tissue, though they are requisite where the amount of substance is appreciable to the unaided senses.

Transverse section of the dense portion of the femur.

Of the substance of Bone, or Hyaline Substance—The substance of bone has been considered, with but one or two exceptions, as homogeneous, and without appreciable structure. If it be examined however under advantageous circumstances, with high magnifying powers, there will be no difficulty in detecting a very definite though delicate structure. A very small portion of a thin plate of bone should be taken for the purpose of examination; such may be found in the ethmoid bone of small animals, as of the rat. If the piece is properly chosen it will be found to contain no Haversian canals nor corpuscles, but will be extremely thin and transparent. A piece of this kind will present a delicate granular aspect with the surface nodulated. This granular appearance proceeds from the substance of the bone being composed of minute irregularly spherical granules. This structure may be traced without much difficulty in any specimen of bone, although it varies much in distinctness in different specimens. The object should be placed between two slips of glass with a little plain water for examination. A delicate spiculum from the point where ossification is going on illustrates the granular tissue exceedingly well. The granules may be obtained separated from each other, so that each individual may be examined independently of the others.

Ultimate osseous granules, obtained by depriving bone of its animal matter.

When seen in this manner they exhibit a tolerably regular character, being mostly spherical, though a few have an oval form. In a few specimens the oval form predominates.

Of the Laminæ.—The forms assumed by the osseous tissue is that of laminae, and these laminae have a definite arrangement, so much so that three distinct systems are recognized, namely: lamina of the Haversian canals; secondly, the lamina which connect the Haversian systems; and, thirdly, the lamina which form the surface of the bone, and enclose the two previous orders. The lamina of the Haversian canals have a concentric arrangement, and when divided transversely present a series of more or less distinct and perfect rings.
They vary very much in number, but the most common amount is ten or twelve. Of these, the internal lamina, that which forms the parietes of the Haversian canal, is most distinctly marked, while each succeeding one as we proceed outwards becomes less distinct. Connecting these Haversian systems is a second series of laminae, without which the former would exist but as a bundle of loose tubes (Fig. 27, c). In this substance we find the laminated arrangement less distinct, far less regular, and the laminae individually subject to great irregularity of thickness. They are generally more transparent than either the Haversian or external system. The last division consists of those laminae which surround the exterior of the bone. These have greater individual extent, but are the least numerous. They are continuous with the lamina of the Haversian system whenever the latter arrives at the surface of the bone; the external lamina if this case being continuous with the inner lamina of the Haversian system.

The effect of madder upon the osseous system, when given to an animal with its food, may here be noticed, since the colour is imparted to the laminae. By introducing madder into the stomach, a deep red tinge is very soon observed: in a pigeon the bones were rendered brilliantly red in twenty-four hours. A similar effect was produced on a young pig in three weeks. On making sections of bone so affected, the colour is found to be present in the external lamina of the bone, and in the inner lamina of the Haversian system, thereby proving that the action of colouring takes place upon those surfaces which lie in contact with vessels.

Of the Haversian canals. These canals must be considered in relation to their number, their size, and the parts which they contain. The number of canals in a given space vary perhaps a little, but this variation will be regulated in some degree by the situation of the bone, but more especially by its age. Thus the transverse section of the femur of a human foetus of seven months will present many more canals than a section of equal measurement from the femur of an adult. The size of the Haversian canals takes a considerable range, varying from the 500th to the 600th of an inch. The Haversian canals undoubtedly convey passage to blood-vessels, these being their principal if not only purpose.

The corporaee or cells of bone cannot be described as having any definite unvarying shape or size. The general form is a compressed oval, though not uncommonly they are circular. Again, they are sometimes almost triangular in their outline, while in other instances they approach a linear shape. These are the most common varieties of outline to which the bone-cells are subject, as they occur in the bones of man and the higher animals. In the four great classes of animals, namely mammalia, birds, reptiles, and fishes, it has been shown by Mr. Quettet that there are certain characters connected with these cells by which a bone of one class may be distinguished from that of another. He has shown that they are smallest in birds, a little larger in mammals, and largest of all in the reptiles; while in fishes they are altogether unlike those in the preceding classes. The importance of this observation in relation to fossil remains is obvious.

Connected with the cells are numerous delicate branching tubes, which are slightly dilated as they enter the cells. The number arising from each cell does not allow of any very definite enumeration; but, as in two cells we have found, perhaps, of a like number of branching tubes. The general arrangement of the tubes is radiates as regards the cells which form their common centre. The connections are so numerous between the tubes, that a fluid introduced into one cell in a bone, may enter every other cell in that bone. The cells are situated between the laminae, or on their surface; but where concentric laminae occur, as in the ilium, they are placed in circular lines between the laminae, each line of cells having the Haversian canal as an exit common to it and the connecting lamina. When the canals for vessels are in great abundance, the bone-cells are more rarely met with; indeed in some cases they are almost entirely absent.

When the cells are seen by transmitted light, particularly in a transverse section of bone, they are frequently opaque. There is no doubt that the bone-cells perform the function of circulation.

The Chemistry of Osseous Tissue has recently met with much attention from Valentin, Lehmann, Marchand, and more especially Von Bihr. From the bones of the human body has aged forty years, who committed suicide, Lehmann obtained—

For a full account of the chemistry of bone we must refer to Simon’s ‘Chemistry,’ vol. ii. pp. 396-414, or Von Bihr, ‘Chemische Untersuchungen der Knochen,’ &c., Schweinfurt, 1844.

9. Tooth. The structures entering into the composition of the teeth are three: dentine, or tooth-substance; enamel; and cement, or more properly tooth-bone. The enamel invests the more prominent parts of the crown, from which points it gradually diminishes in thickness, till it terminates in a line on the neck of the tooth. The cement, or dental bone, is thickest at and near the end of the root, and gradually becomes thinner as it advances towards the crown of the tooth. In a tooth that has been used for some little time, the cement terminates where the enamel commences, but there is reason to believe that a thin layer is continued over the enamel. Of these tissues, dentine, as forming the great bulk of the tooth, and thereby becoming the most important, will first demand our attention. The pulp-cavity occupies the centre of the dentine, and on its surface are superimposed the enamel and the tooth-bone. By drilling the crown and the latter the surface of the fang. These two tissues form a layer of variable thickness in different parts of the teeth. This layer, however, is soon worn off when the tooth comes into use.

If the enamal and cement be removed from a tooth, and the dentine alone allowed to remain, the tooth still retains much of its original shape, losing most at the two extremities, while in point of size the loss sustained is comparatively slight; thus showing the dentine to constitute by far the greater portion of the tooth.

The dentine is made up of two distinct parts: first, dentinal tubes; secondly, intertubular tissue. The tubes have distinct parietes, equal in thickness to their calibre. In some instances they appear to contain a minute granular matter, but in many, perhaps in the majority of cases, they are perfectly free from solid contents. The tubules, in section, are elliptical, being for examination, the dental tubes may be traced from their commencement on the surface of the pulp-cavity, to their termination at the junction of the cement, and the dentine on the enamel of the last of the tubes that have been passing into these external structures. The tubuli commence at a right angle with the surface of the pulp-cavity, and proceed outwards towards the surface of the tooth, giving off in their way numerous small branches, which form yet other similar branches from neighbouring tubes, anastomose with them, or meeting with simple cells in the intertubular tissue, there terminate. Towards the surface of the dentine it is not uncommon to see a tube after its course, by forming another, form a loop. The tubes all communicate in the pulp.
cavity, and pass outwards towards the surface of the dentine. Their course, as regards each other, is divergent, so that the proportion of the intertubular tissue increases relatively as their distance from the pulp-cavity is greater or less. This preponderance of the intertubular over the tubular tissue near the periphery of the tooth is, however, in a considerable degree lessened by the more frequent branching of the tubes, and by the occurrence of cells near the surface of the dentine. If a single tube be traced through its whole extent, it will be found to make two undulations; and in addition to these, which are called the primary curves, a number of smaller undulations. In examining this structure a thin section may be taken from the face, and, with the aid of the microscope, viewed by transmitted light. A tube will then appear as a very definite dark line pursuing its tortuous but definite course towards the surface, giving out numerous minute branches on its way, and at last dividing into two terminal branches, which either by passing into a cell of the intertubular tissue, or by anastomosis with a collateral tube, or by passing into the cement. If a section of the dentine and enamel be taken, then the tubes will be seen to give off comparatively few branches till they come near to the latter, when they divide and subdivide, and some few terminal branches may be traced entering the enamel. It is by no means uncommon for a tube in its course to suddenly dilate and give off branches from the dilatation, then again contract, and pursue its original course. In such a case the dilatation forms a cell in every similar way to the bone-cell. The point of the greatest diameter of the dental tubes is at their commencement on the walls of the pulp-cavity, though in their course proceeds to the division of the trunk into two terminal branches they suffer but little loss in calibre. In tracing this structure in the teeth of various animals, we find every form of branching; sometimes the branches are few, in others extremely numerous; in some instances they are given off from one side of the tube only, in others from each side; but whatever the modification in the number or form of the branching given out, the primary tube always commences by an open extremity on the walls of the pulp-cavity, or into the walls of a canal for a blood-vessel; and the direction taken by the tubes is invariably towards the periphery of the tooth, always Anastomosing in their way by the numerous branches.

In the temporary, and not unfrequently in the permanent teeth, the tubes, instead of presenting an uninterrupted line, present on their surface numerous indentations, just as though they were covered by a thin layer of a mass of minute hollow tubes, which were united and made to communicate with each other.

The second part composing the dentine is the intertubular tissue, which occupies the spaces between the tubuli, everywhere surrounding and investing them, and thereby contributing greatly in rendering the whole dentine a solid dense mass, the area of the tubes and cells being the only hollow portion. In a favourable specimen of this tissue Mr. Temes observed that it was composed of very minute granules, united to each other on all sides, thus forming a solid mass, of which, in character of formation, oolite would give a coarse illustration. The granularity is best seen near the external surfaces of perfect dentine, or in the tissue when developing. In the intertubular tissue, hemispherical or oval bodies are found, especially near the surface of the dentine of the fang, where they form a layer joining the cement.

**Structure of the Enamel.** — The enamel is the hardest of the dental structures, and being composed of dense, hard, fibrous, placed side by side, and closely united. Their form is an approximation to a six-sided prism, and their size is tolerably uniform, being about the eighth of an inch in diameter. The direction taken by the enamel-fibres is the most part vertical to the surface of the dentine upon which they rest; those therefore which proceed from the flat surface of the crown will rise vertically, while those from the lateral surface of the tooth will be horizontal. When the coronal surface of the dentine is concave, the enamel fibres of the opposite sides of the concavity form with each other angles, and meet at their external ends. This juncture is frequently imperfect, and leaves a fissure, under which the dentine, being less protected from external influence than on the other parts of the crown of the tooth, is more frequently attacked by disease. The fissures on the crown of the molars are often subject to this defect of development. The ends of the enamel fibres are received into shallow hexagonal depressions in the coronal surface of the dentine, from whence in their course they are frequently described. The direction taken by neighbouring fibres is sometimes perfectly parallel; indeed, they often diverge or cross each other at considerable angles. The curves also seem less regular than those, which are formed by the dentine tubes.

**The Bone or Cement.** — Where the anterior parts of the crown of the fang, on entering the cavity of the bone, the cement commences in a layer, gradually increasing in thickness to its termination at the apex of the root, although a very thin (radulminate) layer is continued over the crown, investing the enamel. The histological characters of this structure are so completely identical with those of ordinary bone that we need offer no additional remarks on them.

For the importance of the microscopic investigation of the teeth in the classification of existing and the determination of extinct species of vertebrated animals, we must refer to Professor Owen's "Osteographie," one of the most splendid works ever published.

**Chemistry of the Dental Tissues.** — Von Bibra has instituted numerous analyses of the teeth of man and the lower animals. We select the following by way of illustration:

The osseous portion includes the dentine and cement.

We have thus taken a brief survey of the microscopic and chemical characters of the most important structures entering into the composition of the human body. In addition to, and perfectly distinct from these are numerous morbid products—the results of disease. In this class we must place pus, granular cells, the various forms of morbid tumours, the calculus of the tubercle, sequestrous bodies, &c. These however are not fall within the scope of this article; and for information regarding them we must refer to Vogel's "Pathological Anatomy of the Human Body," an English translation of which has recently appeared by Dr. Day.

**Section III.—Nutrition and the Secretions.**

We shall here notice those points in the chemistry of the blood—the general nutrient fluid—which the labour of recent investigators have evolved since the publication of the article Blood, P. C., and adopt a similar course in relation to the various secretions thus deduced by it.

We shall, in the first place, however, offer a few remarks on nutrition in connexion with nutrition, with the view of bringing into the article Food, P. C., up to the present state of our knowledge. That all nutrition in the body is based on the use of food is not at present adopted by chemists and physiologists, but is not yet completely understood.
There are very strong reasons for believing that foods containing nitrogen are alone capable of conversion into blood, and of forming organised tissues; hence Liebig has termed them the *plastic elements of nutrition*. The non-nitrogenous foods are, according to Liebig, incapable of transmutation into blood, and are therefore incapable of forming organised tissues. They are, however, not without their use; their function lies, according to Liebig, to support the process of respiration (Diathesis). A supplementary food is necessary to attend to the development of heat. These latter foods he terms the elements of respiration.

- Nitrogenous Foods or
  Proteins of Nutrition.
  Vegetable fibrin.
  Vegetable albumen.
  Vegetable casein (casein).

- Non-nitrogenous Foods, or
  Elements of Respiration.
  Fat. Peetine.
  Starch. Bassorine.
  Gum. Wine.
  Grape-Sugar. Spirits.
  Sugar of Milk.

Liebig believes that a second use (an abnormal rather than a natural one) of the second group is in relation to the formation of fat (p. 636). Moreover, the statement contained in the article Fats, that 'gelatin is a highly nutritious principle,' requires some notice. Liebig has established it as a law that 'no nitrogenized compound, the composition of which differs from that of fibrin, albumin, or casein, is capable of supporting the vital processes in animals.' The animal organism, he says, 'unquestionably possesses the power of forming from the constituents of its blood, the substance of its membranes, as of cellular tissue, of the nerves and brain, of the organic part of cartilage and bones. But the blood must be regarded as already formed in everything but form—
that is, in its chemical composition. If this be not done, a period is rapidly put to the formation of blood, and consequently to life.' For this reason gelatin, which, as we have already shown (p. 638), is not a protein-compound, cannot form blood, and therefore will not support the vital processes. The two following facts seem however to show that it has a use in the economy:—1. When in the body of a starving or sick person the fat disappears, and the muscular tissue again takes the form of blood, we find that the tendons and membranes retain their natural condition, and the limbs of the dead body retain their connexions, which depend on the gelatinous tissues.—2. On the other hand, the gelatin of bones devoured by a dog entirely disappears, whilst only the bone-earth is found in the excrements. The same is true of man when fed on food rich in gelatin; as, for example, strong soup. The gelatin is not to be found either in the urine or in the faces, and consequently must have undergone a change, and have served some purpose in the animal economy; in other words, it must have been expelled from the body in a form different from that in which it entered it. From these facts Liebig inclines to the belief that gelatin is serviceable in the formation of cellular tissue, membrane, and cartilage; and that it may tend to the reproduction of such parts of the body as has been mentioned. The gelatinous tissues.

4 And when the powers of nutrition in the whole body are affected by a change of the health, then, even should the power of forming blood remain the same, the organic force by which the constituents of the blood are transformed into cellular tissue and membranes must necessarily be enfeebled by sickness. In the sick man the intensity of the vital force—its power to produce metamorphoses—must be diminished as well in the stomach as in all other parts of the body. In this condition, the uniform experience of practical physicians shows that gelatinous matters, in a dissolved state, exercise a most decided influence on the state of the health. Given in a form adapted for assimilation, they serve to hasten the vital force, just as may be done in the case of the stomach, by due preparation of the food in general. Britteness in the bones of the ground-living animals is clearly owing to a weakness in those parts of the organism whose function it is to convert the constituents of the blood into cellular tissue and membrane; and if we can trust to the reports of physicians who have resided in the East, the Turkish women, in their diet of rice, and the Arab, their flesh, and the condition necessary for the formation both of cellular tissue and of fat. Whether this be the mode in which gelatin acts or not, no one who has seen much medical practice will deny that it is of the greatest value in such cases.

We now proceed to make those additions to the chemical portion of the article Blood which the labours of the last ten years have rendered necessary.

We have already (in our remarks on isolated cells) noticed the additions that have been recently made to our knowledge regarding the blood-corpuscles of various animals. Numerous observations have also been made on the changes in form which the corpuscles undergo in various diseases (Simon's 'Animal Chemistry,' translated, with additions, by Day, vol. i. p. 103, London, 1845; published by the Sydenham Society); also on the effects of various medicines and re-agents on the corpuscles ('An. Ch.,' pp. 107-112). Additional information on the acceleration or retardation of the coagulation may be found in Hambberg's Thesis on that subject published at Uppsala in 1839, and in Simon, 'An. Ch.'

With regard to the chemical composition of the blood, we may regard it as usually containing the following ingredients:

1. Water.
2. Protein compounds. Globulin.
3. Colo...
is dependent on the presence of tribasic phosphate of soda (2 N a O, H O P O 3) ; and as this is the only salt that remains tribasic at a red heat, he concluded that the alkalinity of the blood, as well as of the ash, is dependent on it. The manner in which he accounts for the occurrence of carbonates in the analyses of other chemists is very plausible. On exposing 2 N a O, H O P O 3 O s and N a O, C O 3, or phosphate of soda in which one atom of the base is replaced by an atom of water and carbonate of soda.

This operation causes the salts actually occurring in the blood is however far from settled, Ludwig having during the last few months positively denied Enderlin's statement; (see also C. l., 1846.) Generally speaking it is only possible to analyze in the blood, to determine a few of the most important constituents; as, for instance, the water, fibrin, blood-corpuses (globulin and hematin), and the solid residue of the serum (the organic portion and the salts). For this purpose we may adopt the following simple plan lately published by Fugier. It is based on the fact made known many years ago by Berzelius, that after the addition of a solution of a neutral salt to defibrinated blood, the globules do not (as before) pass through a cycle of filtration. On the addition of two parts of solution of sulphate of soda of specific gravity 1130 to one of blood, Fugier found that the whole of the corpuscles remained on the surface of the filter. The following are the stages of the process. The filter is rinsed, dried, and weighed; the weight of the corpuscles is ascertained by the method indicated, and that of the albumen by coagulating by means of heat the filtered solution. The proportion of water is determined by evaporating a small quantity of the weight of the blood. The filter containing the corpuscles should be dipped in boiling water, which removes any sulphate of soda that may be present, and at the same time renders the corpuscles insoluble. The weight and frequently different processes are requisite to detect those ingredients which occur in small quantity or only in morbid conditions.

Distinctions between Arterial and Venous Blood. — We have already (p. 882) pointed out the circumstance that the external capillary of the blood-corpuses becomes converted during the act of respiration into oxidized protein, and that the bright red colour of arterial blood is owing in part to the modifying influence of the white investing membrane. But there is yet another mode in which it acts. The buffy coat which is frequently observed on the upper part of the clot in inflammatory diseases is very apt to curl up and become concave. Now this buffy coat consists, for the most part, of the oxides of protein — of the very same matter with which the blood-corpuses become invested. For this reason the form assumed by the two laminae on both sides of the little flat body — the corpuscle — results from the action and influence of the buffy coat. The corpuscles and become bi-convex is so strong, that the central portion of the crust becomes entirely depressed. In this form the corpuscles reflect a great deal more light than when, in consequence of the removal of the buffy coat in the capillaries, they have a less bi-concave form.

From analyses of the blood of horses, Simon deduces the following rule regarding the chemical differences of arterial and venous blood. The arterial contains less solid residue generally than venous blood; it contains less fat, less albumen, less hematin, less extractive matter and salts, than venous blood. The blood-corpuses of arterial blood contain less colouring matter than those of venous blood. The arterial blood was taken from the carotids, and the venous from the jugulars.

Composition of healthy human venous Blood. — In a medical point of view the composition of venous blood is the most interesting, because it is from the veins that blood is almost always taken in disease, and because venous blood can naturally only be compared with venous blood for the purpose of ascertaining any deviations that may occur. The following table represents the mean composition of human venous blood without reference to sex:—

<table>
<thead>

100 parts of blood-corpuses contained 0-7 of hematin. Hence the blood contains about 20 per cent. of solid constituents, and between 0-2 per cent. of fibrin, and about an equal quantity of fat; the blood-corpuses considerably exceed the albumen in quantity, and contain about 5 or 6 per cent. of colouring matter.

The following table shows the proportions in which we are limited precludes us from noticing the various modifications which the blood undergoes in different forms of disease. The extent of these variations is obvious from the following table, drawn up from Simon's "Animal Chemistry," vol. i., p. 245.

Lymph and Cyste. — Closely allied to the blood are the lymph and cyste. These fluids have only recently been submitted to correct chemical examination. In Simon's "Chemistry" the reader will find recent analyses of the former by Marchand and Colberg, L'Heritier, Rees, and Nasse; and of the latter by Simon, Rees, and Nasse.

From the comprehensive classification of the blood we naturally turn to that of the various secretions yielded by it.

The saliva has been analysed by Simon, L'Heritier, and Wright. The following is Dr. Wright's account of healthy saliva. It is of considerable importance, and worth being always remembered after a meal during fasting. Healthy saliva has mostly the specific gravity of 1007-9. When above 1010 or below 1008 it may be considered morbid. Healthy saliva is either alkaline or neutral, generally the former. He believes in the existence of the principle termed ptyalin, although he separates it from the saliva by a new process, which is to pass saliva through ordinary filtering paper, and after filtering it has been accounted for mainly by ptyalin, which residue with sulphuric ether: the ethereal solution contains a fatty acid and ptyalin. It is to be allowed to evaporate spontaneously, and the residue left by evaporation is to be placed upon a filter and acted on by distilled water, which dissolves the ptyalin and leaves the fatty acid. On evaporating this solution to dryness the ptyalin will be obtained in a pure state.

In relation to the presence of sulpho-cyanogen Wright remarks that it is a constant ingredient of the saliva. The proportion, he observes, is temporarily augmented by local stimulation of the salivary glands, as by smoking, chewing salaments, &c. It is also increased by the internal use of arsenic acid and salts of cyanogen, and remarkably so by the use of sulphur. The occurrence of this substance in the saliva is equally interesting in a physiological and in a medico-legal point of view. The circumstance that it forms with the prussic acid a much cheaper blue-red of a beautiful color in which the cyanate of iron, must not be overlooked in examining the stomach in a case of suspected poisoning by opium.

L'Heritier has recorded the mean of 10 analyses of the saliva of healthy persons, made while fasting.

The ptyalin formed 2-6 of the 12-6 parts of organic matter.

Mialhe has recently (April, 1845) announced the discovery in the saliva of an active principle analogous in its physical and chemical characters to opium. It is solid, white or greyish white, amorphous, insoluble in alcohol, but soluble in water and in weak spirit. The directions for obtaining it are the following: filter saliva and treat it with five or six times its weight of absolute alcohol, adding it as long as any precipitate occurs. This animal diastase falls in white flakes, which when stirred together with Tolu 0-2 parts of water. The Bile. — It would take up far more space than we could devote to the subject to notice all the additions that have been recently made to the chemistry of the bile. In the year 1838, Denarrove published a treatise on the mastication of organic acid combined with soda. He termed the acid chochic, and obtained it in the following manner: bile, from which the mucus had been precipitated by evaporating on the water-bath, and 10 parts of the dried residue were dissolved in 100 of water, to which 10 of hydro-
chloric acid had been added. Allowing evaporation at a moderate temperature to proceed, it was observed that a dark green oil collected on the surface, while at the same time the fluid remained cloudy, and the remaining fluid to rest for some time, it gradually became clear, with the precipitation of a green deposit. This dark green bitter precipitate is Demarcay's chloric acid, and is regarded by him as consisting of the chloric acid of the urine. The granules of this acid still mixed with maragace, choleretic, pigment, &c. After their removal it forms a yellow spongy matter, which rapidly absorbs oxygen from the atmosphere, is very bitter, slightly soluble in water, and insoluble in alcohol.

The choleate of soda, obtained by adding an alcoholic solution of soda to an alcoholic solution of choleic acid, and then passing a current of carbonic acid through it to remove the excess of soda, possesses all the characters of bile; it yields on evaporation a brown resinous mass, and is soluble in water and in alcohol.

When choleic acid is boiled with hydrochloric acid it yields ammonia, taurine (see Taurine, P. C.), and choloidal acid; the latter being insoluble is deposited. The former usually assigned to choleic acid, taurine, and choloidal acid are, \( C_6 H_{10} O_3 \), \( C_6 H_{12} O_5 \), and \( C_7 H_{14} O_7 \).

But it has been recently shown by Redtenbacher that the formula for taurine should in reality be \( C_7 H_{14} O_7 \); since it contains no less than 28-6 per cent. of sulfur which had been previously altogether overlooked (Leylb and Wollweber, Arch. f. Physiol., vol. 145, 1845). Hence there can be no doubt that the formula for choleic acid also requires considerable modification. For further information on the recent history of the chemistry of the bile we must refer to the works of Leylb and Wollweber. The following description of the microscopic and chemical character of healthy human bile is condensed from a series of papers on the subject by Freerick (Annales, 1845, 2, 17-27; Day's 'Reports on the Progress of Animal Chemistry,' in Ranking's 'Half-yearly Abstract of the Medical Sciences,' vol. III., and 'On the Size of the Cellular Constituents of the Bile.' The bile is always a deep brown, but when seen in thin layers it has a brownish-yellow tint. It is very fluid, being viscid only in new-born infants. The specific gravity varies from 1.023 to 1.040. On examining with the microscope bile from the gall-bladder, with which, of course, a certain amount of mucus is mixed, there are observed:—1. Transparent or greyish-round vesicles, about the 700th of a line in diameter; they disappear on the addition of alcohol or ether, and are removed by filtration. 2. Conical yellow bodies, about the 140th of a line in length, and about the 300th or 400th of a line in breadth, apparently devoid of nuclei; these are epithelial and resemble those of the Malpighian vesicles of the renal tubules. 3. Irregular dark granules, which disappear on the addition of alcohol or ether.

4. Occasionally minute crystals of choleretic, occurring as colourless rhombic tableaux.

The chemical characters are shown in the following analyses.

Platner has recently succeeded in obtaining cholic acid and choleate of soda in a crystallized form.

The bile is a transparent fluid, intended to remove effete matter from the blood, but that it is a secretion essential to the animal economy, was rendered almost certain by the experiments of Berzelius, Thayer, and Schlösser, which are now confirmed. On the basis of these experiments it is thought that each animal has always a certain quanta of the substance resembling bile, to fix the idea that it is evaporated in this manner. A further proof that the bile is absorbed and not excreted is afforded by an examination, made by Enderlein, of the ash yielded by the contents of the different portions of the intestinal canal of a hare. He found that from the ash of the contents of the duodenum alone effervesced on the addition of an acid, such as the choleate of soda (which yields the characteristic odor of the bile), on the addition of alkali, reaching the jejunum. Schwann has recently established this opinion beyond a doubt, by a series of well-observed experiments on dogs. He tied the ductus choledochus, and at the same time formed a communication to the intestines of the biliary duct, to which the bile escaped externally. His most important conclusions are, 1st, that when the bile does not get into the bowel its absence is generally perceptible in dogs about the third day, by a marked diminution of weight; and, 2ndly, that unless the channel for the conveyance of bile to the duodenum is re-established symptoms of deficient nutrition, wasting, debility, &c. ensue, and death is the ultimate consequence.

The chemistry of the bile remains to be revised; it has been recently made the object of especial study by Blundell, Bernard and Barrow, Misaelis, and Dr. A. D. Thompson, who have obtained very contradictory results.

The work has been recently examined by Simon, Clement, and Dunns. The reader will find a copious account of the chemistry of this secretion in Simon's 'Animal Chemistry,' vol. III., pp. 49-89.

The urine has, since the publication of the work of Ewarz, P. C., been made an object of especial investigation by Leylb. The most important fact that has been discovered is that hippuric acid is, although in small quantity, a constant ingredient of the urine. This urine is a secretion peculiar to the kidney, and depends in a great measure, according to that chemist, on the property that uric and hippuric acids possess of combining with the potash or soda of the alkaline phosphates, and thus forming hippuric acid phosphate, which is excreted. The brief space necessarily allotted to this article has renders it imperative on us to omit the consideration of many points of very high physiological importance.

For further information on the subject we must refer to the proceeding pages we must refer to the following works:

1. On the Structure of Animal Tissues—Henle's 'Allgemeine Anatomie,' the article 'Tissue' (Gewebe) in Wagner's Handwörterbuch der Physiologie; Bever's and Todd's 'Physiological Anatomy and Physiology,' the works of Drs. Carpenter; Goodricke's 'Anatomical and Physiological Observations; the articles 'Muscles, Membrane, ' on Tissue, in Todd's 'Cyclopedia of Anatomy and Physiology,' and Mr. Tome's 'Lectures on Dental Surgery' in the 'Medical Gazette' for 1845-6. The best account in the English language of vegetable tissues is given in Henfrey's 'Structural and Physiological Botany.'

2. On the Chemical Department of this article we must refer to Simon's 'Animal Chemistry'; to Dr. Day's Reports on the Progress of Physiological and Pathological Chemistry, in 'The Half-yearly Abstract of the Medical Sciences;' to Leylb's 'Animal Chemistry,' translated by Gregory; to Mulder's 'Versuch einer Allgemeinen Physiologischen Chemie;' to Lehmann's 'Lehrbuch der Physiologischen Chemie;' and to Lieb's 'Traité de Chimie Pathologique.'

TLEMSEN. ['Algiers, P. C., p. 480.]

TOD, JAMES, Lieutenant-Colonel, in the service of the East India Company, was born in 1792, in England, and educated in Scotland. He went out to India in 1800, and obtained a commission in the 3d Bengal European regiment; thence he volunteered for the Moulmeen, was transferred to the marines, served as a mariner on board the Mornington, and, in 1805, when in the subsidiary force at Gwalior, in Hindostan, was attached, under his friend Mr. Gurney Mercer, to the embassy sent at the close of the Mahratta war to the court of Sindia in Mewar, where the embassy arrived in the spring of 1806. Rajpootana, of which Mewar is one of the states, thenceforward became the scene of his official labours, as well of the geographical, historical, and antiquarian investigations by which he distinguished himself. He made several surveys of Rajpootana soon after his arrival in the country, and the result of those surveys was the magnificent map which is the present at the commencement of his 'History of Rajpootana.' The map was completed in 1815, and was presented to the Marquis of Hastings, then governor-general of India, and it was of great use in forming the plan of operations in 1817, on the previous day, which was imperfect and erroneous. In 1817 he was appointed political agent, with the entire control of five of the states which had then just placed themselves under British protection, Mewar, Marwar, Jessulimur, Kotah, and Boondee. The results of
his investigations into the geography, history, and antiquities of Rajpootana are given in his 'Annals of Rajasthan.' Regarded as the historian of the country, it is necessary that he should return to the more congenial climate of his native country. Previously however to his departure from India, he made a circuit of nearly the whole of Rajpootana, which he completed at the close of 1822, and in the beginning of 1823 he sailed from Bombay, and arrived safely in England.

After his return to England his time was chiefly devoted to literature. He was elected a Fellow of the Royal Asiatic Society. In 1834 he went to the Continent for the relief of a complaint in the chest, and remained abroad twelve months. He returned to England in September, 1835. While he was occupied with 'Travels in Western India,' the result of the journey which he made previous to his return to England, and especially his observations in Gujerat, the last chapters of the work were written in October, 1858, while residing with his mother in Hampshire, and the MS. is said to have been left nearly fit for publication except filling up a few blanks and the completion of the engravings; but it has not yet been published.

On the 16th of November, 1838, while transacting business with his bankers in London, he had an attack of apoplexy, and lay without consciousness for twenty-seven hours. He died November 17, 1838, at the age of fifty-three. He left a widow, the Revd. Mrs. Heber, and a family. Bishop Heber, who travelled through Mewar and the adjoining Rajpoot states, in 1826, on his way to Gujerat, bears testimony to the affection and respect borne to Colonel Tod by the Hindoo inhabitants, and when in various towns through which the bishop passed. He says, 'Here and in our subsequent stages we were continually asked by the cut- wals, &c. after Tod Sahib (Captain Tod), whether his health was better since he returned to England, and whether there was any chance of seeing him again. On being told it was not likely, they all expressed much regret, saying that the country had never known quiet till he came among them, and that they expected either rich or poor, they were all exceedingly dear, loved him. He, in fact, Dr. Smith told me, loved the people of this country, and understood their language and manners in a very unusual degree.'

Bachelors, a commercial town, which had contained 12,000 families, had been entirely ruined by the depredations of the Maharrattas at the time when Colonel Tod was appointed political agent. He set himself to restore it, and in less than a year there were seven hundred prosperous and peaceful families in it. Colonel Tod, in a letter to a friend, says, 'Regarding Bachelors, the work of my hands, in February, 1818, there was not a dog in it; in 1825 I left 8000 houses, of which 1200 were bankers and merchants.

The place was in the hands of the 1st and 2nd Light Dragoons and deserted by his inhabitants, when Captain Tod persuaded the Rana to adopt measures for encouraging the owners of land to return, and foreign merchants to settle. He himself drew up a code of regulations for them, and obtained them an immunity from taxes for a certain number of years, and sent them patterns of different articles of English manufacture for their imitation. He also gave money liberally to the beautifying of their town. In short, as one of the merchants who called on me said, 'It is thought ought to be called Todgurze, but there is no need, for we shall never forget him.'"

The 'Annals of Rajasthan' were published in London, in 2 vols. 1833; in 1834, and in 1838. He was educated at Hertford College, Oxford, where he proceeded M.A. in 1786.

He became a minor canon of Canterbury Cathedral soon after he returned to England. In 1792 he was elected a Fellow of the Royal Society, and in 1793 he was appointed by the Archbishop of York to the prebend of Husthwaite, in that cathedral church; and, finally, in 1832 he was appointed Archdeacon of Cleveland.

His attention was, from the commencement of the Deans of Canterbury, from the new foundation of the Church by Henry VIII., 5 vols., 1793. This was followed by an edition of Milton's 'Masque of Comus,' with notes and illustrations, 1 vol. 1801; 'The History of the Life and Writings of John Milton,' with notes and a life, 6 vols. 1801, for which he received 2000l. from the booksellers, and of which there was a second edition 4 vols. 1806; 'The Poetical Works of John Milton,' with notes and a life, 8 vols. 1806, reprinted in 1846; 'Illustrations of the Lives and Writings of John Gower and Geoffrey Chaucer,' 8 vols., 1810; 'A Catalogue of the Archiæpaliscæ Manuscripœs in the Library at Lambeth Palace,' fol., 1819 (600 copies privately printed); a new edition of Dr. Johnson's 'Dictionary of the English Language,' with corrections and additions, 8 vols. 1814, &c., and again in 3 vols. 1827; 'The History of the College of Bishops, Bishops and Archbishops of Canterbury, for the Earl of Bridgewater'; 'Original Sin, Free Will, Redemption, Faith, Good Works, and Universal Redemption, as maintained in certain Declarations of our Reformers,' &c., 1819; 'Manners and Customs of the Tribes and Translators of the Bible' (in reference to Bellamy's new translation), 8 vols., 1819; 'Observations on the Metrical Version of the Psalms, by Sternhold, Hopkins, and others,' 8 vols., 1821; 'Memorials of the Life and Writings of Bishop Heber, Bishop of Chester,' 3 vols. 1822, 1824, 1825; 'An Account of Greek Manuscripts of the late Professor Carlyle, now at Lambeth,' 6 vols., 1828 (privately printed); a new edition of 'The Doctrine of the Sacrament,' 8 vols., 1826, with a Vindication of Cramer, reprinted in 12mo. in 1826; 'A Letter to the Archbishop of Canterbury, concerning the Authorship of Iden Basili, &c., 1825 (assigning the work to Bishop Gauden); 'A Reply to Dr. Lingard's Vindication of his History of England, as far as respects Archbishop Cramer,' 8 vols., 1827; 'Bishop Gauden the Author of Iden Basili' further shown, in answer to Dr. Wordsworth,' 8 vols., 1829; 'Life of Archbishop Cramer, 2 vols. 1831 (an enlargement of the 'Vindication'); 'Authentic Account of our Authorized Version of the Bible,' 12mo., Malton, 1864. We have only to add that the whole of the papers and portions of literary works here published are in the possession of Mr. Heber, who also, in the early part of his literary career, a frequent contributor to the 'Gentleman's Magazine'; and he is stated in his obituary notice to have been a member of the Kent Philosophical Society, and to have assisted largely in the preparation of that work.

Archdeacon Todd, who was a Chaplain in Ordinary to her Majesty, died at Settrington, on the 24th of December, 1845.

From Hereford he took the direct route which is given in the 'Gentleman's Magazine' for June, 1846, he appears to have left several daughters.

Archdeacon Todd, though the editor of Milton and Spenser, had no pretensions to either poetical talent or poetical taste; but nor was even his acquaintance with our old poetry, or with our old literature in general, very extensive or intimate. His annotations, accordingly, are rather dry. At the same time, if they do not overflow with much variety of knowledge, and rarely display, any remarkable ingenuity, they do not annoy the reader by any kind of superfluous discursion. He is certainly not a very animated narrator; but he facts may generally be found in their proper order, and after the words, perhaps, have been rendered in the field of bibliography.

(Memoir in Gentleman's Magazine for March, 1846.)

TOFIELDIA, a genus of plants belonging to the natural order Compositae, and family of the Asterales, is generally burting longitudinally. The three capsules, connected to above the middle, are 1-celled and many-seeded.

T. patula, the only British species, has pedicles naked at the top, and is a species of T. patula, the flowers are from 4 to 8 inches high, the leaves sword-shaped, about 2 inches long, in 2-ranked radical tufts. The flowers are in a dense spike, at first sessile, afterwards slightly stalked with a bract at the base. It flowers in November, and is native of the perianth.

(Behington, Manual of British Botany.)

[Previous text]
1845, all corporal tenements and hereditaments shall, as regards the conveyance of, be immediately conveyed by the delivery of the deed of conveyance, as incorporeal hereditaments and reversions and remainders of corporal hereditaments are passed, such delivery to every deed to be effectual as a grant, being the same as if the same had been a release founded on a lease for a year, and also with the stamp-duty (exclusive of progressive duty) with which such leases for a year have been chargeable. For and in consideration of the conveyance of a fee simple or any less estate, the only operative word now necessary to be used is 'grant.'

By section 3, a feoffment (unless made under custom by an infant) is to be void unless it be by deed; and a person in possession, and an exchange, or lease required by law to be in writing, an assignment of a chattel interest, a surrender in writing of an interest which could not be made at law without writing, or in any tenements or hereditaments not being copyhold, is to be void at law unless made by deed. The only effect of this section with respect to most of the matters comprised in it, is to assimilate the law to the practice, and with respect to others, to require to be made by deed. The reason of this distinction seems to be that in the feoffment the essential part is not the execution of the deed, but the delivery of the possession or seisin from the foother to the feoffee.

A feufo de男 to have any estate, conveyance, and an exchange or partition is not to imply any condition in law; and the word 'give' or 'grant' is not to imply any covenant in law beyond what it already has under any Act of Parliament, (section 4). This provision points to the old common law doctrines, that a feoffment, though made by a person having no title but possession, had the tortious effect of passing the fee, and that warranty was implied from the use of the technical words 'exchange,' 'give,' and 'grant.' A saving clause has been rendered necessary by the introduction into certain Acts of Parliament containing short forms of conveyance, and providing that, to save expense, the word 'grant' is not to mean any more than is necessary.

By section 5 it is enacted that under an indenture an immediate estate and the benefit of a condition or covenant may be taken, although the taker be not named a party: and a deed purporting to be an indenture is to have the same effect as an indenture, although not indented. This abolishes the distinction between an indenture and a deed-poll, whereby a person in possession is entitled to a fee simple, and under it except by means of the Statute of Uses; whereas any person might take under a deed-poll, which is addressed to all the world. The latter clause of the section merely expresses the intention by which it is enacted.

By sections 6 and 7, contingent interests, possibilities coupled with an interest and rights of entry, whether immediate or future, and vested or contingent, in tenements and hereditaments not being copyhold, are not to be excluded, but no such disposition is to defeat or enlarge an estate tail. These provisions extend to married women, who are likewise enabled to disclaim by deed, but all deeds executed by them must be indented, and no formerly to the parties of the first description. One object of the first of these clauses is to remedy a deficiency in the Act for the Abolition of Fines and Recoveries, which provides for the conveyance of contingent estates both in fee simple and in any other species of contingent estate. Under this clause also the assignee of a right of entry has power to enter for a breach committed before the assignment. The second clause is also intended to remedy an omission in the Fines and Recoveries Act.

By section 8 a contingent remainder existing at any time after the passing of this act, is to be deemed to have been, capable of taking effect notwithstanding the determination by forfeiture, surrender, or merger of any preceding estate of freehold, in the same manner as if it had been created by a previous disposal. As that part of the 7 & 8 Vict. c. 76, relating to contingent remainders, was repealed as from its commencement, it was necessary to provide for those cases in which property had been vested in a contingent remainder before the provisions of the Act are effectuated by making the clause in question relate as well to those contingent remainders existing at any time after 31st December, 1844, as to those created before the passing this act. The force of this clause will be understood by referring
TRANSIT, RAILWAY.

An article intended to be supplementary to that given under RAILWAY, P. C., pp. 245-267, and to treat especially upon matters which have risen into importance during the seven years which have elapsed since that article was written, many topics which seem to claim attention must be passed over, or treated very briefly. Excepting in the simple historical portion of the subject, almost every line that has been referred to presents matter upon which something might be said indicative of the rapid progress of mechanical improvement, or of the results of extended experience; but our attention must be confined to a few only of the more important points relating to railway legislation, and to the construction, working, and management of railways, together with statistical notices of the progress of the railway system in the United Kingdom, France, and other countries, over the whole face of Europe, and of the civilized world. To facilitate reference we shall, as far as the nature of the subject permits, follow the order of arrangement established in the earlier part of the volume, but the reader may readily trace the connection between the original and the supplemental matter. The principal deviations from this course are in the bringing together, under the general head of "finance," the whole matters of the obtaining of railway acts, originally noticed under RAILWAY, pp. 251, 252, and such as relate to government control, taxation, &c., which were noticed in pp. 260, 261 of that article; and in the incidental notice in connection with the important question of gauge, of various matters relating to general principles of railway construction, working, and management.

Railway Legislation.—The growth of Railway travelling in this country has been so sudden, and its consequences, in relation to the interests of the public, were so little foreseen at its commencement, that until very recently it has advanced without control, and, it may be said, almost without the notice of the Government.

There are two opposite principles of administrative policy which may be pursued in reference to undertakings of public utility. By the one all such works are executed either directly by the Government or under Government superintendence; by the other they are the result of private enterprise, and Government has no further concern with them than to see that they are executed by those who have the means necessary for their execution. In countries where capital is not abundant, nor the spirit of commercial enterprise very active, the former principle is often essential for the promotion of public works, and in the case of the railways and canals of France, Belgium, and Germany; but where the speculative energy and resources of capitalists are so remarkable as in England, no encouragement is needed from the Government, and its interference is required only for the protection of public interests. The circumstances of this country, therefore, would naturally have dictated the policy of protecting the investment of capital in public undertakings, with as little restraint as possible; and our free institutions, and the generally passive character of our Government, have favoured politically a principle which would have been considered a dangerous one in the United States. The question may be doubted, indeed, whether this principle has not been carried too far; and whether capital would not have been invested more beneficially under a surer and more provident system of legislation.

The following is a sketch of the proceedings which have been necessary for carrying out a scheme of railway communication. The parties who have planned it obtain subscriptions to the undertaking, and having ascertained the surveys and satisfied themselves of the profitable character of the speculation, they determine to apply for an Act of Parliament to incorporate a company for executing the works, and to give them the powers required for that purpose. The most important power to be obtained is that of taking lands and houses without the consent of the parties interested in them; and in the early period of railway legislation, the only opposition encountered by railway companies was that of the landowners, who were either unwilling to sell their land or dissatisfied with the price which had been offered them. If this opposition was overcome or conciliated, the bill was allowed to pass. If no such opposition was offered, and if there were no competing lines, no means were taken by Parliament to inquire whether the line was the best that could have been suggested to the public; but if the promoters intended to pass; but the evidence adduced by the promoters was held to establish the public utility of the undertaking, and it was authorised. The executive government took no part in the investigation of the several quotes for the public interest; and so little was the character of railway communication understood, that in fixing the tolls and charges, parliament at first named a maximum for the tolls, as in the case of canals, but that idea was afterwards abandoned, and the existence of goods and passengers. As the companies undertook the entire traffic of their own lines, no tolls were payable, and the maximum, which was intended for the security of the public, was wholly ineffectual. This oversight has since been rectified, and every railway act of 1845 and 1846, whether for a new line or for an amendment of acts, under which existing lines were constructed, contains a clause which reserves to Parliament the right of revising the rates and charges; and in most of the recent acts the maximum charges are moderate. In 1838 committees were required to give their opinion on government representations, but their proceedings were improved by this regulation in form rather than in substance. In 1839 the constitution of the committee was improved by the admission of "selected members," who were not interested in the undertaking, and the committees have been composed exclusively of members who have had no local interest in the lines referred to their consideration. But however these tribunals may have been improved, the same system of legislation has practically prevailed. Unopposed lines have, almost without exception, been sanctioned upon the ex-parte evidence of the promoters; and opposed lines have been granted or refused according to the relative wealth, influence or perseverance of the contending parties.

It is undeniable that more vigilance ought to have been exercised in investigating the merits of lines, and in securing the best terms for the public which were consistent with justice and fairness; while, on the other hand, the promoters of railways ought to have been protected against the ruinous waste of capital which has been occasioned by various forms of procedure, and by ill-regulated and too often incompetent tribunals.

But notwithstanding admitted defects in the system of railway legislation, the principle of allowing free scope to the operations of private enterprise and capital has been eminently successful, and more railways have been constructed in the last fifteen years, and more science and enterprise have been displayed in all branches of transport, than a government could have called forth in half a century. Nor have the public interests otherwise suffered so materially as might have been anticipated; for the conditions, for the public good, which might have been made the
subject of express regulation, have in great measure been secured by the operation of the same principle. The charges upon goods and passengers, for example, which might have been expected to have accompanied the track, have shown a considerable tendency to decrease. The competition of canals and steam-boats, the profits to be secured by the encouragement of increased traffic, the dread of competing lines, the example of other lines already constructed, and other circumstances, have already caused a very general reduction of railway charges, and may eventually lead to still more extensive reductions.

This acknowledgment is due to the spirited and able capitalists, who, under a defective system of legislation, and without any aid or direction from the government, have done so much for the prosperity of the country that it has been impossible to overlook many serious evils which have arisen from the want of a uniform administration of railway affairs:—1st. Parliamentary committees, however well conducted, are independent of another, are guided by no uniform principle, have no peculiar experience, and are devoid of all means of obtaining any other information but that which is offered by the parties themselves. 2dly. Great powers are required by companies for executing their works and conducting their business, in granting which considerable caution is necessary. 3rdly. When the acts for incorporating companies have been passed, it is desirable that every railway should have the power and right to send trams from being exceeded, or extended injuriously. The whole traffic of the country is rapidly being absorbed in railway communication, and so enormous a public interest needs the utmost care of the government to guard the public safety and convenience, a quite compatible with a respect for the freedom of capital.

Having stated these general principles in reference to railway legislation, we may proceed to a brief analysis of the views entertained by different railway companies from time to time for the supervision of railways and for other purposes connected with the general administration of railway affairs. The objects for which they were passed are not always analogous, but it will be convenient to offer a consecutive view of them, as, however imperfect they may be, they constitute, in effect, our whole railway code.

The first step towards a control of railways by the government was taken in 1840, when an act was passed to place them under the supervision of the Board of Trade (§ 4 & 5 Vict. c. 97). By this act it was provided, that no railway should be opened until a month's notice had been given to the Board of Trade; that returns should be made by all railway companies of their traffic, of accidents, and of their tolls, rates, and charges; that the Board of Trade should be authorized to appoint inspectors to examine railways; and that all bye-laws should be submitted to the Board, who may disallow them. These and other matters provided for by this act, at once disturbed the independence under which the railway system was growing up, and placed the affairs of all the railways under the immediate supervision, and, in some degree, under the control of government.

By the act 5 & 6 Vict. c. 55, power was given to the Board of Trade to prohibit the opening of any railway not considered safe by their inspectors: notice of accidents attended with serious personal injury was required to be given to that board within forty-eight hours after their occurrence, and the Board were further empowered to direct returns to be made of all accidents, whether attended with personal injury or not. With a view to the public safety, disputes between railway companies having a common terminus, or using a portion of the same line of rails in common, were to be decided by the Board of Trade; and all powers, under existing acts, of making branch communications with railways, and of running locomotive engines upon them, were submitted to their regulation. They were also authorized to enforce the alteration of level crossings which appeared to endanger the public safety.

The provisions required all railway companies to convey Her Majesty's Forces and the Police Force at such prices and upon such conditions as may be contracted for by the secretary at war.

The provisions of these acts were mainly directed to the ensuring of the public safety; but in 1844 a more important act (7 & 8 Vict. c. 85) was passed with a view to secure, as far as possible, the interests of the public from being sacrificed to the privileges granted to railway companies, or from the attempts of railway companies to avoid the payment of due compensation to the property, to companies. With this object the following securities, amongst others, were provided. If after twenty-one years from the passing of the act the construction of any new line of passenger railway the clear annual profits divivable upon the paid-up capital shall have exceeded 10 per cent. upon the average of the three preceding years, the Treasury may revise the scale of tolls and charges, or may require such revision; and if, upon paying to the Treasury 10 per cent.; with a guarantee, however, that 10 per cent shall be made good to the company, and that without their consent no further revision of their charges shall be required for three years. And whatever may be the rate of divisible profits at the expiration of the twenty-one years, the Treasury may purchase any such railway, in the name and on behalf of her Majesty, upon giving three months' notice, and on paying for 25 years' purchase of the annual profits estimated on the average of the three preceding years; subject to arbitration however, in particular cases, and to certain exceptions. And in order to give effect to these provisions full powers are given to examine all the books and accounts of the companies for three years preceding the time at which the tolls may be revised or the railway purchased. For reasons which are well explained in the second report, the Railway Committee of 1846, it is doubtful if these prospective securities will ever be available; but immediate advantages were also secured to travellers and to the government.

In order to provide for the poorer class of travellers the means of travelling by railway at moderate fares, and in carriages protected from the weather, it was enacted that every railway company should provide one third-class passenger train, at the least, all along the line where two or more passengers are carried, and under the following conditions:—

1. The hour of starting to be subject to the approval of the Board of Trade.

2. The speed shall not, upon an average, be less than 18 miles an hour for the whole distance travelled, including stoppages.

3. The train shall, if required, take up and set down passengers at every passenger station.

4. The carriages shall be provided with seats, and protected from the weather in a manner satisfactory to the Board of Trade.

5. The fare of each passenger shall not exceed 1d. a mile.

6. Each passenger shall be allowed to take half a cwt. of luggage, not being merchandise or other articles carried for hire or profit without extra charge; and no excess of luggage is to be charged by weight, at the lowest rate charged for passengers' luggage by other trains.

7. Children under three years of age, accompanying passengers, are to travel without charge, and under twelve years of age, at half price.

With the exception of the fares, which are in no case to be exceeded, the Board of Trade were empowered to dispense with any of these restrictions where they considered the arrangements made by railway companies, which may appear more beneficial and convenient for the passengers by the cheap trains. And as an encouragement to cheap trains, it was further provided that there should be levied by each railway company, which arise from the conveyance of passengers at fares not exceeding a penny a mile.

If any passenger train shall run on Sundays on any railway, subject to the above provisions, it is required that a sufficient number of third-class carriages shall be attached to the train which stops at the greatest number of stations, and that the passengers shall be carried, as in the cheap trains, at fares not exceeding a penny a mile. By the act 5 & 6 Vict. c. 79, the duty upon passengers conveyed by railway is chargeable at the rate of 5 per cent. upon all sums received or charged for the hire, fare, or conveyance of such passengers, was 21,826l. (Parliamentary Paper, 1846, No. 606.)

By an act of the 1 & 2 Vict. c. 98 provision had been made for securing advantageous arrangements upon railways for the conveyance of mails, and by this act additional facilities were given for that purpose.

In regard to new railways also, a further provision was introduced in respect to the conveyance of troops, requiring the privilege of occupying railways of the Parliament, in time of war, on duty to be conveyed in a first-class carriage at fares not exceeding 1d. a mile, and every soldier or policeman, and their wives, widows, and children above twelve years of age, in a carriage provided with seats, and protected from the weather, at 1d. a mile;
children under three years being taken without charge, and under twelve at half price, as in the case of the cheap trains. The company are required to convey military stores, baggage, and troops, by facilities for the employment of the military being given in loading and unloading them; and gunpowder and other combustible matters at such prices and under such conditions as may be contracted for with the secretary. It was also enacted that every railway shall be bound to allow a line of electric telegraph to be laid down for her Majesty's service upon lands adjoining the railway, and to give every facility for erecting and maintaining it; and such telegraphs being erected, to such reasonable remuneration as may be agreed upon, or, in case of disagreement, as may be settled by arbitration. Such telegraphs, subject to the prior use of the government, may be used by the company for the purposes of the railway, upon terms to be agreed upon or settled by arbitration. And where an electric telegraph shall have been established by the railway company, or by any company or person, otherwise than exclusively for the public service, or exclusively for the purposes of the railway, or jointly for both, the use of it, for the purpose of receiving and sending messages, shall be open to all persons alike, without favour or prejudice; but subject to priority of use of government and the railway company, and to such equal charges and reasonable regulations as may, from time to time, be made by the company.

The direction of the lines of railway has been given to the Board of Trade to appoint persons to inspect railways, and by this act the board were empowered to appoint permanent inspectors, not only to inspect railways, but also to enable the Board of Trade to provide for the protection and preservation of the railway acts. This enactment resulted in the nomination of the Railway Department of the Board of Trade, of whose functions and proceedings we shall presently have to speak. Whenever it shall appear to the Board of Trade that the provisions of any acts for the regulation of railways have not been complied with, or that the companies have been acting in a manner unauthorised by such acts, or ought to be re-promulgated or stringent, the Board of Trade shall certify the same to the Attorney-General for England or Ireland or to the Lord-Advocate of Scotland; who shall proceed against such companies at law or in equity, as the case may require.

A practice had arisen of issuing loan notes not authorised by the acts under which railway companies were empowered to borrow, and by this act the issue of such notes in future was prohibited, but validity was given to those which had been already issued, and companies were authorised to renew them for five years after the passing of the act. A register of such loan notes was, at the same time, required to be kept by the secretary of the company.

A remedy was also provided for the speedy recovery of tithe-rent charges payable upon lands which had been taken for railways.

The experience of railway companies who had applied to parliament, from time to time, for powers to make and maintain their lines had suggested various clauses which were usually adopted in all railway bills. These were very numerous, and in some cases contained provisions which obtained an act to authorise its own separate undertaking. These powers, though generally very similar in all cases, were sometimes varied by the parties applying for acts, and such variations were sanctioned by parliament. In this matter not only was a want of uniformity occasioned in the powers given to parties engaged in precisely similar undertakings; but all these important provisions were contained in local acts. Little known was the partial proclamation of another inconvenience of less consequence, arising from this system of legislation, was the necessity of repealing in every railway act the related multitudinous enactments.

To remedy these inconveniences several acts were passed in the session of 1845, which are now commonly called the 'Consolidation Acts.' The first is the 'Companies' Clauses Consolidation Act, 1845 (8 & 9 Vict. c. 100), thereby consolidating all the provisions which had usually been inserted in acts with respect to the constitution of companies incorporated for carrying on undertakings of a public nature. This act is not peculiar to railway acts alone, but which apply to parliament for incorporation, and which require the powers contained in it. It regulates the distribution of the capital into shares, the registry of shareholders, the transfer of shares, the power of the company to borrow money, their general meetings, the votes of the shareholders, the appointment and rotation of directors, their powers and proceedings, the appointment and duties of auditors, the accountability of the officers of the company, the form of books of accounts to be kept, the declaration of the settlement of disputes by arbitration, the service of notices upon the company and by the company upon shareholders, and the recovery of damages and penalties. By a similar act (c. 17), provisions of a like nature have been enacted with reference to the taking of lands for undertakings of a public nature. It provides for the purchase of lands by agreement, for the compulsory purchase of lands and the assessment of their value, for the form of conveyances, the entry upon the lands of the promoters of the undertaking, and for dealing with the various interests in land, as copyholds, common lands, mortgages, rent-charges, leases, &c. A similar act for the same purpose was passed for Scotland (c. 18). These acts are also applicable not only to railways but to all other undertakings in which compulsory powers of taking land are necessary.

The last act of the series is the 'Railways Clauses Consolidation Act' (c. 20), which consolidates all the usual provisions of previous railway acts, which relate generally to the construction and maintenance of roads, the drainage of lands affected by the railway, the temporary occupation of land during the progress of the works, the crossing of roads, the construction of bridges, and the works required to preserve the peace and quiet of the surrounding districts. It regulates the traffic in goods and passengers on the line, and prescribes the use of suitable carriages and engines.

These acts did not affect the provisions of local acts which had been passed before the session of 1845; but the acts of that session and all subsequent acts have simply adopted the three consolidation acts without repeating them, and where any special powers not contained in these acts are sought for by the parties, they are contained in distinct clauses, which are obvious variations from the ordinary law.

In the same year it was observed that various railway acts of that session had given to companies general powers of granting or accepting leases, sales, or transfers, of their own or other lines of railway; and as the exercise of such powers without control was regarded with jealousy, as being liable to lead to an amalgamation of lines, for which separate acts have been passed, without the distinct authority of parliament being obtained, in each case; an Act (8 & 9 Vict., c. 96) was passed, declaring that no such sale, lease, or transfer, should be lawful, unless under the authority of a distinct provision in some act of parliament, to that effect, specifying by name the railway to be leased, sold, or transferred, and the company or party by whom such lease, &c., may be made, granted, or accepted.

Another act must here be referred to in connexion with railways. The 'Joint Stock Companies' Act of 1844 (7 & 8 Vict., c. 110), though applying generally to another class of companies, provided that names of companies relating to railways. Before the passing of this act, it was only necessary for railway companies to comply with the standing orders of both Houses of Parliament before they applied for a bill to authorise the undertaking; but other conditions must now be complied with. Before the promoters of a railway may publish any prospectus, handbill or advertisement, they must return to the Registrar of Joint Stock Companies, 1st, the proposed name of the company; 2nd, its business or purpose; and 3rd, the names, occupations, &c., of the promoters; and either before or after the prospectus is published, they must return their provisional place of business, the names of the committee, &c., with a written consent of each promoter to become such, and an agreement to take one or more shares; the names, residence, &c., of the officers of the company; and a copy of the prospectus itself before it is circulated or made public. When the three first particulars, at least, are complied with, the promoters are entitled to receive a certificate of provisional registration.

The promoters may then assume the name of the proposed company ' provisionally registered,' and may open subscription lists, and allot shares and receive deposits not exceeding the nominal value of the shares to be issued, for each 10s., 1l., or other share capital as may be required by the standing orders, and may perform all the acts necessary for obtaining an act of parliament.
In order to obtain a certificate of complete registration, the company must send to the register a copy of the 'Parliamentary Contract,' and the 'Subscribers' Agreement,' together with certificates of the deposit, at the proper offices, of the money required by the act, conditioned with the payment of the interest and the redemption of the deposit. When the certificate has been obtained, the promoters may use the name of the company 'registered,' may have a common seal, may sue and be sued in their registered name, and may enter into contracts, conditionally upon the passing of the act, for the execution of works, for the supply of stores, or for any other necessary purpose of the company.

Subject to these conditions the companies must comply with the standing orders of both Houses of Parliament. The committee of the House of Commons, and apply for bills to incorporate them and authorise their undertakings.

In the session of 1846 several acts were passed affecting railways. The first (9 & 10 Vict. c. 20) introduced an improved method of effecting the deposits of moneys required by the standing orders of Parliament, to be deposited by the subscribers to undertakings; and granting the privilege of depositing Exchequer Bills and other public securities instead of money. This act was rendered necessary on account of the great inconvenience sustained by the promoters of railway bills and by the public, from large sums of money being suddenly withdrawn from the money market which were locked up unprofitably in the hands of the accountant-general of the Court of Chancery, and were not very readily invested in government securities.

The second (9 & 10 Vict. c. 29) facilitated the dissolution of railway companies which had not on the 3rd of July, 1846, obtained acts of parliament to authorise their undertakings, and placed the form and proceedings under which such dissolution should be effected.

The third is an act for constituting Commissioners of Railways, which transfers to the commissioners to be appointed all the powers and duties of the Railway Department of the Board of Trade. The commission is to consist of a president, with a salary of 2000l. a year, two paid commissioners, with salaries of 500l. each, and two unpaid commissioners. The president and the two paid commissioners will be qualified to sit in Parliament; but the two paid commissioners will be disqualified.

In addition to the ordinary powers of the Railway Department they are to examine and report upon any subject relating to any railway or proposed railway, which shall be specially referred to them for their opinion, by Her Majesty or by either House of Parliament. And authority is given them, for that purpose, to inspect and survey any proposed line of railway, with all the powers possessed by the officers engaged in the Ordnance Survey, and to charge the expenses to the promoters.

These are the several statutes relating to railways; and a few remarks will be sufficient to explain their general operation and the proceedings which have been adopted for carrying into effect their provisions. It has already been stated that, by virtue of the act of 1844, the Railway Department of the Board of Trade was constituted. Its general object was to enforce the provisions of that and other acts, and to report to Parliament its own proceedings, the progress of railway communication, the accidents which occurred, and other matters which come within its cognizance. Its functions were originally confined therefore to the general supervision of railways already authorised by Parliament; and although railway bills were then sent to the Board, it was not the doctrine of the Board took no active or ostensible part in reference to railway schemes about to be submitted to parliamentary investigation; but in consequence of the recommendations of a select committee of the House of Commons in 1844, the Board was instructed by the Lords of the Committee of Privy Council for Trade to undertake a preliminary examination of all railway schemes, to publish their decisions in the 'London Gazette,' and subsequently to submit detailed reports for the information of Parliament. This plan of investigating railway schemes, which was perhaps a departure from the preceding practice, was not without its difficulties. It had been tried in the case of the four competing lines to Brighton in 1836; and in respect of the communication between London, Dublin, Edinburgh and Glasgow, and more extensively in regard to the railway communication of Ireland, in 1837; but this was the first experiment that had been made of a systematic investigation of all railway schemes by a government department, in anticipation of the formal examination of the scheme by the House of Commons. The committee of the Board of Trade, in their views, lay down the general principles upon which they intended to proceed, but they had not anticipated the positive manner in which the House of Commons would be likely to receive their proposals. The committee of the Board of Trade was dissolved by a resolution of the Commons, and the railway bill was referred to a select committee of the House of Commons, who proceeded with the investigation of the several bills very much in the same manner as if no reports had been made by the Board of Trade, and their guidance. The decisions of the Board of Trade may have been influenced by the reports of the Board, but the reports themselves, though ably written and often of the highest value, were not founded upon a public examination of the facts. The Board of Trade was a body of men who had that account did not obtain such confidence as to be held conclusive, when interests of such magnitude were concerned.

And it may be doubted whether, under any circumstances, any body which is so strong and irresponsible than parliament itself, could at that time have withstood the manifold influences of railway companies and speculators. At all events this experiment of the railway department was admitted to be a failure, and by a statute of 1845, it was abolished. The Privy Council for Trade, of the 10th of July, 1845, the Board has since directed its attention to questions affecting the public safety and to considerations of public utility, but has in no case pronounced an opinion on the actual or comparative merits of any railway schemes. During the whole of the session of 1846 there was an unprecedented pressure of railway business before parliament, but without any aid from the government it was disposed of, in the usual manner, by committees. It has been stated that all the powers of the Railway Department of the Board of Trade have been transferred, by Act of Parliament, to the Board of Trade; and it is most probable that the experiment of reporting upon the merits of railway schemes, which failed before, may now be revived; but under the act it will be confined to such cases as may come under the consideration of the Board of Trade or the House of Parliament. The difficulty which existed before in giving to the degree of authority which preliminary inquiries and reports should possess still remains, it is feared, as great as ever. The power of the Board has been greatly increased; and as conclusive of the matters referred to their consideration, the intolerable evil will exist of three distinct investigations before three tribunals, and at an enormous expense to the promoters of railways. The decisions of the commissioners may be reversed by the Commons, whose decisions again may not meet with the concurrence of the Lords; and thus after three inquiries a bill may be lost at last. The only mode of avoiding this evil, which was produced by the system of exhaustive preliminary inquiries, is to refer questions of fact to the investigation of the commissioners, and to hold their reports as final in all cases. It will be necessary, also, that their inquiries shall be of a more public and judicial character, in order to secure public confidence.

Principles of Design and Construction.—Under that division of the article Railway there is a consideration of what is considered as the character of the designing of a railway, it is shown that the tendency of experience was rather to lead to economy in the original cost of railway works by the adoption of comparatively steep gradients, than to the expense of using the most easy route, and to the obtaining of a very level road. In the new railway schemes which acts have been obtained since 1840 the result of the modified opinions of engineers upon this point is apparent in the fact that in 1844, 1 in 100, 1 in 120, and 1 in 150, 1 in 100, and, in several cases, of still steeper slopes, which, by
allowing a nearer adherence to the natural surface, leads to considerable saving of expense in comparatively easy countries, while it allows the conducting of railways in many cases through districts which, a few years since, would have been deemed utterly impracticable for manual labor. The North British and Caledonian railways, passing through a mountainous country where, notwithstanding the introduction of gigantic engineering works to improve the gradients, several long and steep slopes occur, are exactly fitted to it. In this line, especially very formidable slopes were found inevitable, those between Beattock and the summit of the Clyde pass, a distance of nearly 14 miles, averaging in 1 in 97, and comprising an ascent of 1 in 65. In the same district, another example is given, on a smaller scale, in which experience has proved that with engines of suitable construction, a line with an average rise of 1 in 100 for upwards of 4 miles, part of which has a slope of 1 in 80, and which, owing to the peculiarly difficult nature of the country, forms a continuous series of curves of smaller radius than is usual upon locomotive lines, may be worked in both directions with speed, safety, and regularity.

In the Report of the Railway Department of the Board of Trade in 1845 upon projected railways in the Manchester and Leeds district many cases are cited in proof of the assertion that such gradients as were formerly thought objectionable are now adopted every day as a matter of course; and as the capabilities of the locomotive have been enlarged, gradients of a class which would have been considered a few years since as impossible, have been successfully carried even in the Great Western railway. Among the cases cited are the inclined planes on the London and Birmingham Railway, from the Euston Square station to Camden Town, raising in 1 in 59 for 1000 yards and 1 in 49 for 640 yards; and that by which the Edinburgh and Glasgow Railway is conducted into Glasgow, with a slope of 1 in 42 for a distance of 1 kilometer; in all of which the use of stationary engines and ropes had been either wholly or in a great measure discontinued, it being found that the trains could be worked successfully under the circumstances and without expense, as required by locomotive engines. The Lickory incline, on the Birmingham and Gloucester Railway, is likewise referred to as a conclusive proof that a gradient of 1 in 374 for a length of 2 miles 3 chains may be worked by the aid of an engine constructed for the purpose, without serious inconvenience to an extensive traffic; and as a proof that such an incline may be descended without danger by the force of gravity, regulated by the action of brakes.

In reference to curves it is observed in the same Report that practical experience has led to a similar modification of the views formerly entertained. 'The Newcastle and Carlisle Railway,' observes the Report, 'presided to the necessity of constructing some succession of curves, of every degree of curvature, up to 8 chains radius, and with steep inclines, being worked with economy and safety, and upon transverse sections by which the entire gravity was afforded for comparing the two planes; and the evidence of Mr. Gray, who was formerly locomotive superintendent upon that line, shows a decided preference for the cross-sleepers. Mr. Gray observed that with the old sleeper, 'I have,' says Mr. Gray, 'seen the engine going out almost as clean as a new pin, and before half an hour had elapsed you could scarcely see a clean spot on it.' He further states that, having been told by an engine-driver that his wheels slipped more upon the longitudinal timbers than upon the cross-sleepers, he, though incredulous, tried it himself one frosty morning, and found that after the engine, slipping so much upon a level part of the road which was laid upon longitudinal timbers as to lead him to fear that the train would be unable to ascend an incline of 16 feet per mile which it was on the point of being required to do, that the train, laid with cross-sleepers, that the slipping stopped, and the engine 'went up like an arrow.' The slipping re-commenced on reaching another portion of road laid on longitudinal timbers, and again stopped on reaching the cross-sleepers. Upon the Croydon railway, which was originally laid with longitudi-

equally against the jaw of the chair, the middle web of the rail, and its position must be adjusted at the time we write (November, 1845), heavy bridge rails, laid upon cross-sleepers, have been employed.
The kind of rail now most commonly employed resembles that which is stated in the first paragraph of the article on RAILWAY, P. C., which is variously called the I, the II, and the double-T-rail; and the weight is seldom less than 70 or 75 lbs. per yard. In some cases heavier rails have been used; the heaviest used, we believe, being 90 lbs. per yard. Those laid on the Great Southern and Western (of Ireland) Railway, between Dublin and Carlow, by Sir John Macnelli, weigh 90 lbs. to the yard. These rails however are laid in a peculiar method of Macnelli's invention, which was first tried on the Dublin and Drogheda Railway, and in which the use of cast-metal chairs, keys, and pins is avoided, the rails being connected with the sleepers in a more direct and simple manner, which is stated to be highly favourable to security and smoothness of motion.

While longitudinal bearings of timber have lost favour, transverse wooden sleepers, which were formerly regarded rather as temporary substitutes for stone blocks upon embankments and places where sinking might be expected, than as a permanent means of support for the rails, have been brought into very extensive use, and are considered by many to afford the best kind of foundation. The ease with which they are laid, the comparatively small depth of ballast which they require, and their efficiency in keeping the line in gauge, or preserving the direction of the rails, in the event of a change in the level of the material to the fact that the permanent way of the South Eastern Railway, laid under the superintendence of Mr. William Cubitt, is an excellent example of the cross-sleeper construction, which has been exhibited in relaying the Croydon line, and upon some other railways. A minute account of this permanent way, published by Mr. Pope to the Institution of Civil Engineers, in his 'Civil Engineer's and Architect's Journal,' for June, 1842, pp. 290-292, which, as well as a shorter notice in the 'Railway Chronicle' for 1846, p. 299, is illustrated by engravings of the mechanical details. The most striking feature of this construction is the use of sleepers of a regular triangular section, 9 feet long, 11½ inches broad, and 7 inches deep, formed by sawing square blocks of Baltic fig horizontally into four pieces. These are laid with the broadest flat surface (the base of the triangle) uppermost, and the double slope of the under side constituting a form admirably adapted for bedding itself well in the ballast. The chairs, or supports, are produced, cast by Messrs. Ramspeck and May, of Ipswich, of a shape well devised for ensuring sound casting, and obtaining the greatest strength from a given weight of iron, and have a single projecting rib or butting edge, on either side, to engage one of the cast-iron pins. The objective points of support are secured to the sleeper by two pins, one at each end, the holes to receive them being formed alternately on opposite sides of the medial line, so that in a line or tram of the pins may have the least possible tendency to split the sleeper. The joint-chairs, however, or those which are used at the junction of two lengths of rail, have three instead of two holes to receive the fastening pins, which are trent of compressed oak, 6 inches long, and tapering from 1¼ inch to 1½ inch in diameter. The cavity in the chair is so contrived that the rail shall only touch it at two points, the base and the top, at the cheek or jaw, in order that the true angle of obliquity of the rail, and its straightness in the chair, may not be affected by any trifling irregularity of shape; and the rails are secured in place by the pressure of compressed oak, 6 inches long, from each side of the chair. The joint-chair, or section, is placed at a distance of 2 feet 6 inches to 2 feet 9 inches, while the intermediate space is divided into three equal parts. Upon the Croydon line rails of 76 lbs. to the yard, the ordinary chairs 20 lbs. each, and the joint-chairs 26 lbs.; and the chairs and sleepers are placed at an average distance of 3 feet from each other. The gauge of the South Eastern line the rails weigh 70 lbs. per yard, the ordinary chairs 20 lbs. each, and the joint-chairs 28 lbs.; and the chairs and sleepers are spaced at an average distance of 3 feet 6 inches from each other. Upon the South Eastern line the rails weigh 70 lbs. per yard, the ordinary chairs 20 lbs. each, and the joint-chairs 28 lbs.; and the chairs and sleepers are spaced at an average distance of 3 feet 6 inches from each other. Upon the South Eastern line the chairs are placed at a distance of 3 feet 6 inches to 3 feet 9 inches, while the intermediate space is divided into three equal parts. Upon the Croydon line rails of 76 lbs. to the yard, the ordinary chairs 20 lbs. each, and the joint-chairs 26 lbs.; and the chairs and sleepers are placed at an average distance of 3 feet from each other. The gauge of the South Eastern line the rails weigh 70 lbs. per yard, the ordinary chairs 20 lbs. each, and the joint-chairs 28 lbs.; and the chairs and sleepers are spaced at an average distance of 3 feet 6 inches from each other.

In a communication made by Mr. W. H. Barlow to the Institution of Civil Engineers on the 1st January, 1846, and reported in the 'Athenæum' for that year, p. 73, a kind of hollow or tubular key of wrought-iron made to press
progress of the works some of the shareholders became dissatisfied with the increased expenditure involved in the adoption of this greatly enlarged gauge, and at length, in 1869, Mr. F. C. S. proposed that the wider gauge might be adopted. The experiments were carried on in the Great Western line, which was then completed as far as Maidenhead, especially in reference to the new gauge. The results of these experiments were then reported, and there is little difference of opinion among the engineers that the wide gauge, like the lines, would lead to any change in this particular, and consequently the construction of the Great Western line, with its extensions, was continued. In 1870, however, the Cheltenham and Great Western Union line, was completed upon the 7 feet gauge. In the mean time the Eastern Counties railway, another line which was then expected to continue in the Thames valley, was laid with a gauge of 5 feet, which was necessarily followed in the laying of the Northern and Eastern line, after it had been determined to connect it with the Eastern Counties at Stratford. When, however, in 1844, the Eastern Counties company, with which the Northern and Eastern was then amalgamated, obtained powers for extensions which would eventually bring their lines into connexion with the existing lines towards the North of England, the evil of diversity was stopped before any practical inconvenience arose from it, by the expedient of running all trains to and from London upon the national standard of 4 feet 8½ inches; an alteration which, though involving also the modification of all the engines and carriages, was effectuated without stopping the traffic. In the same year, 1844, a branch was opened from the same railway, the Bristol and Gloucester railway, which was originally projected as a narrow-gauge line in extension of the Birmingham and Gloucester, but which, through the influence of the Great Western company, had been laid down on the broad gauge, was opened, and then, for the first time, the evils which had been predicted as likely to arise whenever a break of gauge, or point of meeting between two different gauges should occur, were actually experienced. 

The evidence of the effects of the narrow-gauge system is perhaps most strong where the transfer of luggage of an entire train of much extent, must even in the day-time be an inconvenience of a very serious nature; but at night it would be an intolerable evil: and we think legislative interference is called for to prevent or mitigate such an evil. 

With respect to goods trains also, the evidence of carriers was very decisive as to the evils attendant on any such disturbance and re-packaging as must take place in transferring from one set of tracks to another. Under present circumstances very little re-arrangement of goods takes place in the course of the journey, and even at the important station at Birmingham five-sixths of the goods wagons pass without re-arrangement. In the conveyance of minerals the inevitable expense of the transfer from one set of wagons to another would, without taking into account other considerations, seriously affect the cost of transmission; and the difficulty of shifting cattle would be so great as to present an insuperable obstacle to such an arrangement, from the excited state of the animals after travelling by railway, and the resistance they in consequence offer when it is brought to bear upon them. In reference also to the conveyance of troops the interruption would cause much confusion and delay, requiring, as indeed it does to meet the more ordinary contingencies of general service, a much larger number of engine engines, than the carriers of one company can run over the lines of another.

With regard to the means suggested for remedying or mitigating the evils of breaking gauge, the commissioners express a very decided opinion against the safety of telescopic axles, or couplings by which the wheels of one carriage, or of a whole train, might be shifted at pleasure to suit different gauges, on account of the inevitable danger, to say nothing of the increased expense attending any such mechanism. They also reject as entirely inapplicable to the traffic of railways, the proposal to convey narrow-gauge carriages upon the broad-gauge lines by mounting them upon trucks, an arrangement which could only meet the difficulty as regards a certain portion of the traffic, and that by the conveyance of a large number of engine engines, which required weight and danger. The plan of using shifting bodies for passenger-carriages, capable of being removed from one carriage-frame to another, although practised to a limited extent in France and other countries in which roads are narrow and partly upon a common road, is open to serious objections on the score of insecurity and inconvenience, and it is not expected that the system will be retained in France for long. Of carriage-frames which run in line, and are partly upon a common road, is open to serious objections on the score of insecurity and inconvenience, and it is not expected that the system will be retained in France for long. Of carriage-frames which run in line, and are partly upon a common road, is open to serious objections on the score of insecurity and inconvenience, and it is not expected that the system will be retained in France for long.
sum up their conclusions upon this head by stating their belief that no method had been proposed to them 'which is calculated to remedy in any important degree the inconvenience attending a break of gauge.' In the absence of any evidence of uniformity of gauge throughout the country, the commissioners express their conviction that the time has arrived when, if steps cannot be taken to remove the existing evil of diversity, it appears at least possible the wise measures to prevent it. The question, as applied to the existing state of things in this country, involves, they observe, not only the consideration of the relative length of the lines laid on the two gauges, which, as pointed out by Mr. Wyndham Harding, to enable both engines and carriages to run upon the same line, a plan attended with several difficulties, but which is expected to be adopted in some places where, under present arrangements, the two gauges will intermingle. The difficulty of keeping such a double-gauge road in repair would be serious, and the complication introduced at points and crossings would be very likely to lead to occasional accidents. It is done in the cheapest way, by the addition of a third rail only, carriages of both gauges could not be safely used in one train, because the centre of traction would not be the same, while if mixed engines were used the engine of the narrow gauge would stop short of the line and the complication would be still further increased. This point was illustrated in the evidence of Mr. Wyndham Harding, who showed by a diagram that while at a junction between two lines of ordinary gauge, with two trains running on each, there are only six crossings or intersections of the rails, the number is increased by the addition of two supplementary rails to each track, to twenty-eight. It was further pointed out in the evidence that great inconvenience would attend the use of carriages of different widths on the same line from the circumstance that the station-platforms made to suit the broad would be too far off from the narrow carriages. With regard to the several commendations in connexion with the suggested, enforcement of uniformity, as to what is the best gauge, the commissioners discuss first the question of comparative safety, to which we shall have occasion to advert hereafter, and respecting which they report 'as regards the safety of the passengers no preference is due, with well-proportioned engines, to either gauge, except perhaps at very high velocities, when they think a preference would be due to the broad gauge.' As regards the relative accommodation and convenience for passengers and goods, they consider that the narrow-gauge carriages affording seats for three persons, and giving a first-class, and for four persons, and for the carriage of goods, are rather preferable to the broad-gauge vehicles, which contain only four and six persons respectively in similar cases, because passengers usually like to sit where they can look out, and passengers, the commissioners state, were not likely to take the longer journey by the broad gauge if it were near the latter, even if of equal length, would be the less costly, as well as the less difficult operation. The question of an intermediate gauge is treated very briefly by the commissioners, who, having seen some broad gauge carriages by a partition in the middle, by which the large compartments for eight passengers each are subdivided into two for four each. Until lately the broad-gauge carriages were, they report, 'altogether more commodious than those of the narrow-gauge; but recently carriages have been introduced on several of the narrow-gauge lines nearly as lofty as those on the broad-gauge, and equally commodious.' The evidence as to the comparative ease and smoothness of the motion, which is affected by many other circumstances than the width of gauge, was very contradictory; but upon the whole the commissioners believed, from personal observation on the question, and from the reports of those who have had the most opportunity of comparison, that the smoothness was considerably greater on the broad gauge. For merchandise and mineral traffic the chief bearing of the evidence is in favour of the narrow-gauge small waggon being generally preferred for merchandise of a few hundredweight, in which it is frequently necessary to send wagons partially laden; and also for the conveyance of goods which are liable to injury from pressure. In both kinds of traffic the small vehicles (comparatively small, we should say, the ordinary narrow-gauge waggon being much larger than those used on common roads) appear to be found most convenient and economical. Witness several districts especially, that a smaller waggon can be more easily handled and can be taken along sharper curves than would be suited to a broader waggon; and are therefore more suitable where, as is often the case in such districts, the broken nature of the ground renders curves of large radius inconvenient and expensive. On the whole the commissioners consider the narrow gauge as the more convenient for the merchandise of the country. The observations relating to comparative speed may be passed over with little weight, as the question turns on the relative line the speed both of ordinary and express trains is somewhat greater than upon other lines, the excellence of the gradients, and some other circumstances independent of gauge, the possibility of double-tracking many of the main lines, and the prospective improvements in locomotive engines, analogy would confirm the claim of the advocates of the broad gauge to the power of increasing their speed beyond its present limit, it is not a probable belief that the number of railways would justify the attempting of a higher rate of speed than has been shown to be possible even upon the narrow gauge. In regard to the question of comparative economy the commissioners show that the cost for land, earth-works, masonry, permanent-way, turn-tables, &c., must be greater on the wide than the narrow gauge; that the cost of maintenance must also be somewhat greater; and that the first outlay for engines and carriages is affected in like way by the increase of width. How far this is compensated by the increased power of the engines and capacity of the carriages it is very difficult to ascertain; for in comparing estimates of working expenses obtained from different companies, the circumstances are found to be so different as to render it impossible to deduce satisfactory information with strict reference to the economy of the gauges. By calculations based upon the same data further, they would be led to the conclusion that the average of the cost of the commissioners come to the conclusion that the traffic of the Great Western Railway might, if these lines were altered to the narrow gauge, be worked at about the same expense for the conveyance of goods and for circulating stock, as is the case with the greater trunk-lines of railway, such as are now in practical operation, a superiority due to the broad-gauge system, that superiority would be less for lines yet to be constructed at a small amount of traffic; so that 'the preference were given to the narrow gauge for the existing lines, that system would be still more entitled to the preference for the railways of smaller traffic to which we look forward.' After this, as one of the several important matters, the commissioners observe that, 'estimating the importance of the highest speed of express trains for the accommodation of a comparatively small number of persons, however desirable that may be to them, as far less moment than that of affording increased convenience to the general commercial traffic,' they consider the narrow gauge preferable for public convenience, and, were it imperative in their opinion, would recommend the alteration of the broad to the narrow gauge especially taking into consideration that the extent of the former at present in work is only 374 miles, while that of the latter is 502; the matter is thus reduced to a question of relative cost. The principal question, the commissioners state, is the efficiency of the 4 feet 8 inches gauge, upon both English and Continental railways, was such as to counterbalance any theoretical advantage to be derived from a costly alteration to a gauge of 5 feet, 5 feet 3 inches (which, upon the recommendation of the Board of Trade, had been previously determined as the national or standard gauge for Irish railways), 5 feet 6 inches, or 6 feet, which latter is the largest dimension now adopted by any not directly interested in the 7-feet gauge. They computed that the total expense of altering the then existing broad-gauge lines to the narrow gauge, including the alteration or substitution of locomotives and carrying stock, would cost 'a sum which, however vast, would be lost if the money could not be made to return upon the capital expended.' They neither recommend such an alteration at the public expense, nor conceive that the broad-gauge companies could be fairly required to make it at their own cost, they do recommend to the House of Commons that the subject be referred to the Public Works Committee, with the request that the proportion of cost to be made by the companies and the public be ascertained, and any means be taken to complete the general change of narrow gauge communication from the north of England to the south of Ireland. The commissioners state that the carrying gauge at the junctions to be formed by new lines if laid, as follows: *

* These figures are taken from a return made by the Board of Trade, and are to be corrected, to the 31st of July, 1849. If the openings which have taken place since that time were added, the whole would appear much greater.
on the narrow gauge, with the existing broad-gauge railways, some equitable means should be found of either producing entirely uniformity by the construction of one broad-gauge line, or of adopting such measures as shall admit of the narrow-gauge carriages passing without interruption or damage along them.

The appearance of this report was speedily followed by the publication of the proceedings of the large meeting called, and by the most strenuous efforts on the part of those interested in the broad gauge, to reverse or modify the recommendations of the commissioners, which, it was contended, were drawn up under the influence of three of the commissioners, 'issued' by the broad-gauge party as a kind of counter report, would, if adopted, 'inevitably terminate all chance of future improvements in railway travelling,' by arresting the progress of that company. Several of the companies to which we are undoubtedly indebted for recent achievements in speed, and from which it is pleaded much further advantage may be derived. The report was handed over to the Board of Trade for their consideration, and at a later period of the session of 1846 a bill was introduced, which subsequently became law, founded upon their suggestions. Admitting the general conclusions of the commissioners, the Board appears to have deemed the attainment of uniformity impracticable; and the act for the regulation of gauge therefore simply provides for uniformity upon such new lines as are not directly connected with the existing broad-gauge lines. On the broad gauge, under the acts of 1845, to Rugby and Wolverhampton, and into South Wales; and also in the country lying to the south and west of the Great Western and its extensions limited by the use of railways extending branches of a few miles in length from the Great Western railway, and to such other cases as may be specially sanctioned by parliament. Under the operation of this act, the Birmingham and Oxford Junction line, although projected as an extension of the broad-gauge system, must be laid upon the narrow gauge, unless, as its promoters anticipate, powers for adopting the wide gauge can be obtained in a future session. It is felt by many who have studied the subject, that this compromising arrangement must be regarded merely as a temporary adjustment of the difficulty, and that increased experience will convince even the propriety of the broad-gauge lines of the necessity, for the promotion of their own interests as well as of the convenience of the public, of reducing their gauge to the national standard.

This important subject has already occupied so much of our space, that our remarks, founded upon the instructive evidence which has been brought before the public by the recent investigation, must be limited to two leading points, in both of which the public are deeply interested. The first of these is the increased probability of accidents. Happily the number of accidents which have already happened which can be regarded as even remotely bearing on the question of gauge, is too small to enable us to find any general conclusions upon them. Perhaps the most important that may be developed is that in the cases where due care is exercised, is almost as great as can be expected. The comparative narrowness of base, which, as far as we remember, is the only definite element of danger charged upon the broad-gauge lines, has never been proved injurious in any important degree. Probably no accident has ever occurred of which it can be regarded as the cause, and we are not aware of any in which it can be proved to have increased the damage. On the other hand, it might be difficult to say that any particular accident which has happened upon a broad-gauge line might not have occurred if the gauge had been narrower, the increased width may in many cases be seen to have an injurious effect. The greater weight of the engine and the larger amount of dead weight which, in practice, attends the use of broad-gauge carriages, increases the injury to the track, and from this increase of the distance between the wheels in going round a curve, which frequently leads to collisions, or of giving so fearful a character to many railway accidents. The greater length of the axles, although accompanied by increased braking power, is the most irresistible moment of the gauge, and the strain of which it is one of the small ones would do. Adding to this the circumstance that a curve of given radius is less easily rounded by a broad than by a narrow-gauge carriage, and that the rails are more likely to be deformed at the points of stress, it is evident that even narrow gauges would be amenable to the conclusion that the risks of breaking down or running off the line by the failure of axles are considerably augmented by an increase of gauge. Another circumstance which materially affects this question is the effect of increased width upon the oscillatory or lateral action of the carriages.

A short carriage is obviously more liable to this motion (which, at high speed, becomes dangerous from the danger striking the rails on each side alternately, until at last the motion literally throws the carriage off the rails for a long one; and therefore a carriage suitable for the 7-feet gauge will, unless it be half as long again as would be used upon the 4 feet 8½ inches gauge, be less safe in this respect. Even upon some of the earliest broad-gauge companies this proportion has led to the use of six-wheeled carriages, and such are exclusively used in the fast trains upon the Great Western line; but in order to attain an equal degree of safety in this respect, the broad two systems requires carriages far larger and heavier, as to be difficult to move at stations, where they must often be shifted by hand power, besides involving the conveyance of an enormous amount of dead weight when, as is often necessary in working branch lines, a carriage must be sent through for the accommodation of only two or three passengers. The ordinary second-class carriages of the Great Western line, mounted upon six wheels, are calculated to carry twenty passengers, and are therefore only suitable for a very large and steady traffic; yet in these the length is no greater in proportion to the breadth than in the ordinary second-class carriages for three passengers only on the broad gauge. In goods wagons the same argument holds good with even greater force; while in the case of carriage-trucks and horse-boxes the length of the vehicle is absolutely regulated by the maximum of 7 feet 6 inches, while the distance between the axles is 7 feet. Such a carriage, running as it were broadside foremost, must, at very high velocities, be productive of fearful danger to the train of which it forms a part. The same reasoning will of course apply to the passenger as well as the carriages.

The second point to which we should direct attention is the bearing of the gauge question upon the future prospects of the railway system, not as regards the importance of uniformity, or the comparative cost of construction and working, but as regards the probable advantage of the broad-gauge system. "The traffic of the West of England," observes Mr. Sidney, "requires 'not huge unwieldy carriages and trucks, but handy wagons, which may without inordinate trouble or expense be run into small road stations and sidings, to which a farmer may send his couple of fat oxen, or his score of sheep, or his load of corn, in conjunction with one or two more neighbours.' Of such local traffic, however, there has been little upon the Great Western railway, although it runs through large coal and cattle-breeding counties, because 'the whole machinery is on too vast, costly, and magnificent a scale'; and he conceives the traffic of sad that were it not for the general diffusion of more powerful engines, a gauge of 4 feet 8¾ inches would be preferable for such districts. Mr. Robert Stephenson, in his evidence before the commissioners, referred to a line of about 60 miles laid upon the broad gauge, &c., "the traffic of which has been not more than between 100 and 150 passengers per day. But of the 4 feet 6 inches gauge, he believed, 3 feet 9 inches, which was worked satisfactorily by locomotive engines, both for passengers and goods, and was constructed very economically, as a proof that a gauge of more than 4 feet 8¾ inches was not so advantageous with advantage. In South Wales, where the broad gauge is about to be introduced through the influence of the Great Western..."
company, its unfitness appears even more striking. The mines and iron-works in that district are usually situated in narrow valleys or gullies, in which sharp curves are unavoidable; and, to suit the peculiarities of the country, the local traffic is carried on by narrow-gauge lines, and some of them as narrow as 2 feet 6 inches.

Allusion was made in the course of the gauge evidence to the practice of sending passengers through from end to end of their journey without change of carriage, although they might have to pass over the lines of different companies. Those witnesses who endeavoured to mitigate the evils of gauge passing by the practice of running through lines mutually, for the practice of running through lines must of necessity be in a great measure discontinued. The evidence of Messrs. Brunel and Saunders, the engineer and secretary of the Great Western railway company, was so calculated to convey an erroneous impression as to the practice of the other great companies in this matter, as to call forth an explanatory pamphlet on 'The Origin and Results of the Clearing System,' which is in operation on the Narrow-Gauge Railways, with Tables of the Through-Traffic in the year 1845,' in which it is observed that "No sooner had the railways which extend from London to Liverpool been completed and connected in 1838, than it became evident that arrangements must be adopted to facilitate the passage of the traffic," at the points where the three railways (then under different managements) joined, so that passengers might be permitted to perform any journey with the least inconvenience, which continue by one or more way extended, without being required to change their carriage; and that a similar principle must pervade the arrangements for working every description of through-train if the public accommodation and facilities, and the interests of the railway system developed to their full extent. The importance and at the same time the difficulty of carrying out these principles became more obvious when the lines extending from Rugby and Leamington to York were completed. For some time, however, dissensions arose between the different companies; it was difficult to obtain accurate returns, and payment for the use made by the several companies of one another's carriages and wagons respectively, and some of them came to the end to make an unacknowledged use of the carriages and wagons of others to an extent which amounted to a positive grievance.

Under these circumstances it occurred both to Mr. Robert Stephenson and to Mr. K. Morrison, the present manager of the Railway Clearing-house, that a remedy might be found in the establishment of a central office on the principle of the Clearing-house by which the business of the London bankers is so materially facilitated. [BANK, P.C., p. 385.] After some difficulties the proposed system was, on the 2nd of January, 1849, brought into operation on the railways extending from London to Darlington, Newcastle, Edinburgh, and Edinburgh, and returning by Berwick, Newcastle, Scarborough, Hull, Yarmouth, and Cambridge, to the metropolis; or, in other words, on all the narrow-gauge railways in Great Britain lying north of the Thames, with the exception of the few short ones which are beyond the limits of this account; an area which, it is hardly necessary to observe, is only prevented from extending to the southern parts of England by the intervention of a differential gauge. The fundamental principles of the Clearing-house system, the regulations founded upon which are very rarely departed from, are, that passengers shall be booked through at all principal stations, and conveyed to their destination without change of carriage; that horses and cattle be in like way carried through without change of conveyance, and goods without being shifted or re-arranged; that the companies shall pay a fixed rate for such carriages and wagons, not their own property, as they may need, and a further sum per day by way of fine or demurrage for detention, if kept beyond a prescribed length of time; and that such agreements are to be made in such a manner that the passengers shall pass through the Clearing-house.

Junctions, Station Conveniences, and Signals. Many ingenious contrivances of the switch kind are in use, which may appear to render accidents almost impossible, so far as the action of the movable rails is concerned; but one of the most important precautions attending their use is that now generally adhered to, of 'making all sidings and crossings join the main line in such a way that trains must proceed backwards in order to enter or leave the siding or crossing,' as inserted in the article RAILWAY, P.C., and reversing the position of the arrows in the crossing marked e. The reasons for this precaution will be readily understood. As the diagram now stands, the tracks of the crossing are parallel, and is therefore liable, if they should be accidentally misplaced, to be turned into the wrong track, with imminent danger; but, if, by reversing the position of the arrows, the upper track in the diagram is appropriated to traffic running from e to f, and the lower to traffic running from f to e, it will be seen that (assuming the switches to be, as they usually are in such situations, of a self-acting kind, on the principle of that represented at Fig. 10, upon the same page) instead of the trains being turned into the wrong line, the flanges of the train would open the switch, and it would continue its journey without danger. In order to enter a siding or passing so laid, the train must run past the switches, must then be brought to a stand, and be propelled backwards, by reversing the motion of the engine, when the switches are properly adjusted; but the trifling inconvenience and delay occasioned by this manoeuvre is amply compensated by the greater security afforded by the arrangement to the transit of the ordinary trains, and all such as may have to pass the junction at a moment's notice or consideration of only the speed of any three or alarming accidents, illustrative of the danger of laying sidings into the main line so as to meet the traffic, upon the Brighton, Lewes, and Hastings railway, where, as there was at first a siding extending from the coast, for the purpose of such an arrangement was of course inevitable; while the increasing use of fast or express trains renders it highly important to adopt every precaution which may lessen the risk of running full speed through stations where the use of switches and sidings is necessary. Accidents have occurred through the rolling of carriages from a siding on to the main line by the action of wind, or from some other cause, and thereby exposing passing trains to danger; to guard against which "self-acting clocks have been introduced in some situations. These consist of pieces of bent rail or other iron bar so mounted that, while they may be turned aside out of the way by the wheels of a train, and thus allow a carriage to pass, when the wheel rises up as soon as the carriage has passed, and prevent it from rolling back towards the main line, excepting while they are held back or cleared of the rail by an attendant, by means of a lever handle similar to those used for working switches. Another contrivance, which is sometimes adopted with similar intention to the above, affords the power of laying such tracks as are often required for the purpose of conveying the carriages and wagons from one line to another, without in any way interfering with the rails of the main line. It consists in laying the rails which constitute the cross track for the full length of the main line, and, when the carriage is not required, cutting them off, of course, a little short of the points of intersection. By this arrangement the flanges of a carriage being pushed along the cross track, mounted upon and roll over the rails of the main line, and in running on the cross track the carriage until the wheels again reach the elevated rails of the main line, into the details of the method by which these objects are attained, or the advantages which either have been or are expected to be derived from the establishment of this system, the ultimate result of which will be to go a considerable part of the way towards Great Britain, as far as regards the working of the through-traffic, the character of one concern, conducted on a uniform system, we may state that the tables appended to the present paper show that in the year 1846 these passenger trains were conveyed an average distance of 146 miles each, while the average length of the railways upon which the system is in operation being only 41 miles, each travelled on an average of about 360 miles, by using the junctions or points of convergence; and that to accommodate these passengers, 59,765 railway carriages and 6813 trucks with private carriages were sent through. The tables further show that, in addition to the very large number of wagons used for the conveyance of coke, coal, and other minerals, of which no record is kept at the Clearing-house, 180,806 wagons loaded with merchandise were sent through in a similar manner."
track.

The necessity for breaking the continuity of the main rails by the switching points is thus avoided, and the smoothness of the transit upon the main line is undisturbed.

Some important improvements in turn-tables, tending to diminish the friction and noise occasioned by passing over them, deserve a passing notice. Some are laid with elevated cross tracks of the kind just described, so as to leave the rails of one track smooth and uninfluenced by any number and weight of the vehicles passing over them, or by the shifting of the turn-table being accidentally left in a wrong position. In this contrivance the central portion of the tracks, both of the main and cross lines, is fixed or stationary, the only portion that actually turns being an annular platform, the surface of which is so adjusted to the level of the rails, that a carriage coming upon it when turned into a wrong position would roll over it upon its flanges, coming upon the fixed track in the centre soon enough to avoid any risk of being turned out of its proper course, and, crossing the second half of the annulus again upon its flanges, would reach the fixed track beyond it without being thrown off the track. Some ingenious features of this turn-table, designed to ensure readiness during the passage of a train, are the subject of dispute between Mr. Dunn and Mr. Ellis, the patentee of another improved turn-table.

In the use of efficient signals great progress has been made within the last two years. But when we consider the varying degrees of difficulty of the various turn-tables and the different positions of this character we shall only advert to the admirable system of signals on the semaphore principle, introduced by Mr. C. H. Gregory upon the London and Croydon railway, and which, with various improvements suggested by experience, has been adopted on the lines of the South-Eastern, Brighton, and some other railway companies. The ordinary apparatus mounted at every station, and at each approach to stations of the more important places, is designed to give notice of the two movable arms mounted upon a common pivot near its upper extremity, either of which is capable of being moved independently of the other by means of a handle near the bottom of the post; so as either to hang vertically, in which position it falls into a slant in the post so as to be invisible; to project from it in a horizontal direction, or at an angle of 90°; or to assume a position intermediate between the vertical and the horizontal, projecting downwards at an angle of 45°. Each arm, whatever be its position, refers to its own particular track; that projecting towards the right referring to the right-hand track, and that projecting towards the left to the left-hand track; and when dropped within the post the arm indicates that the line to which it refers is clear, so that trains may pass on safely; when projected horizontally, that a train is a short distance behind the obstruction on the line, or that, for some other reason, any approaching train can cross or overtake, or when projected at an angle of 45°, that, owing to a train being ahead, though at a safe distance, or owing to some other circumstance, the line is closed, and no other train can cross or proceed cautiously until again reaching a signal of safety, or 'all right.' As these semaphore signals can only be seen in the day-time, signal lamps, with powerful parabolic reflectors, and capable, by the turning of handles at the bottoms of the posts, of being shifted so as to throw their light through either a white or colourless, a red, or a green glass, according to whether the signal required be to indicate safety, danger, or the necessity of caution, are mounted near the tops of each post; one lamp directing its light up, and the other down the railway, and each being visible only in its own proper direction, for the guidance of approaching trains. At the junctions of lines on the same ground, but two turn-posts are employed, one for each line, each having two arms, one for the down and the other for the up track of its particular line. The arms and lamps in this case have but two positions, one or the other, and no intermediate position; and the working of the switches and the signals for both lines is effected simultaneously by the hands and feet of one attendant. The engine-driver of every train, on approaching the junction, inclines the lamp to the direction most convenient for him to see in the light in which he wishes to proceed. In addition to these fixed signals, the mechanical details of which are fully illustrated in the 'Railway Chronicle' for 1844, pp. 423 and 415 (from which we have taken the order of these apparatus, for night and day signals, costs about 30l.), hand signals are made by the attendants and workmen upon the line either with the arms alone, with white, red, and green flags, or with red and white lamp, and at such time as a signal is not day-time when are to be passed through, white lamps attached to the front of the engine, and red lamp behind the last carriage of the train, are used as signals with every train, while a green light at the head of the train will indicate trains destined for one line from those of another, wherever, as in the case of the Croydon, Brighton, and South-Eastern lines, the junction of different railways renders such distinction necessary. The red lamp, or a green light, if the train be hung, at the tail of the last carriage of a train, serves to indicate that it is to be followed by a special or express train; and a similar signal attached to the front of the engine of an express train acts as a special warning to keep the line clear on its approach.

In cases where the foggy state of the atmosphere might prevent the signals from being seen, and in other cases of emergency at night, the fog signals invented by Mr. E. A. Cowper are very useful. These are flat circular boxes of about two inches in diameter, filled with an explosive mixture, and furnished with a narrow slip of sheet lead, by which they may be readily fixed upon the top of the rail, in such a position that, when run over by the wheel of the engine, they will produce a loud detonation which warns him to stop. Such signals, with printed directions for their use, are deposited in every station and on the lines by the railway companies; and in case of an accident happening at night, several are fixed at intervals beyond the point of obstruction, so as to give repeated warnings to an approaching train. When the line is clear they may be taken up again and kept for future use. Such signals are used to stop all trains approaching a junction during a fog, until, by the sounding of the engine whistle and of a bell mounted for the purpose at the junction, the nature and duration of the obstruction of the track, and indicates that the line is clear for it.

Carriages. Some remarks having been made on the advantages of increased length in carriages in treating on the gauge question (see p. 667), we need only observe on that point that six-wheeled carriages are now used with advantage upon many narrow-gauge lines, and that still longer vehicles, having eight wheels, and some provision for adapting their sales to a curved track, have been tried, though on a limited scale. In the 'Railway Times' of 1843, pp. 992, 993, are some extracts from a report emanating from the carriage factory of the Leipzig and Dresden railway company, showing carriages of extraordinary dimensions adapted for the German railways, illustrated by an engraving of an eight-wheeled carriage, 47 feet long, and containing seats for 112 passengers. From this paper it appears that bowstrings, which, owing partly to the nature of the German railway line, did not need railway carriages, had not been brought into use so extensively in this country as was anticipated, were greatly preferred in Germany, as indispensible for their effects. In the case of the German.Spring-Carriage, P. C., pp. 387, 388. The inconveniences attending the use of very capacious vehicles for a fluctuating traffic may be met in some measure by extending the plan, which is gaining ground in this country even with carriages of the ordinary dimensions, of combining accommodation for different classes of passengers in different compartments of the same vehicle; a plan which is especially desirable where many branch and connecting lines have to be provided for, to enable the railway companies to send passengers through without a change of carriage, and without involving the conveyance of more dead weight than is absolutely necessary. As a general remark we may say that while the most modern English railway carriages are more elegant in appearance than those of older build, they are both more roomy and stronger in the frame-work, which, in some of the most recently constructed, is made thoroughly as good as can be; experiments or even shown that light carriages would not bear the strains to which they are exposed.

Locomotive Engines. Among the results consequent upon the use of culminating, ground, and the great increase of railway traffic, and the growing demand for increased speed, is a general enlargement of the locomotive engine, usually combined with some deviations from the conventional form; most of these improvements were pointed out in our articles on pp. 559, 560, written. Coupled wheels, which were formerly used mostly exclusively for goods trains, are now
larger and increasingly employed forenger traffic, it become folly to work them at very high velocities. To this change we are inclined to attach considerable importance as a matter of safety, since, independently of the injury done to the road by throwing an enormous weight upon a single point, the wheels, in order to maintain their adhesion, the tendency of the engine to a dangerous rocking motion at high speeds is undoubtedly often increased by that circumstance; for if a disproportionate share of the weight of the machine is imposed upon a single wheel, the two ends will have a degree of play upon their bearing springs which may allow the motion we refer to to increase until the engine is thrown off the rail, as there remains no support for the wheels. Another accident which no obvious cause could be discovered for the engine leaving the rails. There can be no doubt that, with an equal amount of adhesion, a firmer and steadier bearing upon the rails may be obtained when the principal weight is divided between two axles than when it is thrown upon one. The necessity for increased power. calling for the use of larger boilers and cylinders, is resulting to the very general abandonment of that construction of engines in which the cylinders are placed at the bottom of the smoke-box, and the machinery is under the boiler; and a growing preference for those in which the cylinders are fixed outside the frame, and the power is conveyed to the wheels by external cranks and connecting-rods. Engines in which the machinery is thus arranged may be greatly enlarged in all their parts without raising the centre of gravity, the depth required by the smoke-box under the boiler being saved; and they have the further advantages of far greater strength in the axle, and of the whole of the machinery being easy of access for the purpose of examination and repairs. Most important of all, the mechanism perhaps, may be examined and attended to while the engine is running; iron foot-plates, with hand-rails, being constructed along the sides of the frame of the engine. In some narrow gauge engines boilers are used of 3 feet 9 inches diameter, being the largest dimension that the gauge will allow, and the sectional form has in a few instances been made slightly elliptical, the longer axis of the ellipse being placed vertically. In the boiler; but more generally in steam engines the temperature as generated in the fire is maintained by a larger diameter since the economy of fuel is concerned, although, perhaps, looking to the difficulties occasioned by the expansion and contraction of the metal, they may have reached the utmost attainable length with the present construction of boiler. Mr. Stephenson does not state the precise length to which he has extended the boiler; but General Pauley observed that in his long engines it is four or five feet longer than in those formerly used. The distance between the hind and fore axles of the engine to which the accident happened (a six-wheeled one), is 10 feet 6 inches; and from that to 12 feet 9 inches (which, in his evidence before the Gauge Commissioners, Mr. Stephenson stated, was, in his opinion, the great length of bearing of most recently constructed engines for the narrow gauge; while 5 feet 6 inches was the length of bearing formerly employed on the London and Birmingham railway, with four-wheeled engines, though that length has been extended to about 7 feet. Notwithstanding the great length of bearing, the fire-boxes of the long-boiler engines referred to project beyond and overhang the hinder axle, so that the whole length of bearing is as much as twice the length of bearing upon the rails as in the original four-wheeled engines of the Birmingham line, with a bearing of only 5 feet 6 inches. Such large and powerful engines, by which it is anticipated that so much as 2000 tons may be safely attained, are necessarily much heavier than those of the older construction, though, perhaps, not so in proportion to their increased base. The Great Western Company, however, are constructing engines of considerably greater magnitude. The first of these, called the Great Western, accomplished an experimental trip from London to Bristol, in June, 1846, in 2 hours and 26 minutes, including two stoppages, being at the average rate of 58 miles per hour, with a train of ten cars, and 150 tons of passengers. It is a 3.21 mile, at the rate of 51 miles per hour. This engine has about 1750 square feet of heating surface in the boiler; has cylinders of 18 inches diameter and 34 inches stroke; driving-wheels of 4 feet 8 inches diameter. I believe has been the total length is 24 feet; the distance between the supporting wheels 16 feet; the weight of the engine alone, without fuel or water, 284 tons, and of the tender, 10 tons; and the total weight of engine and tender, when loaded, about 56 tons. Whether the railway will be able, without ruinous expense in repairs, to bear the rapid action of so enormous a weight, remains to be seen; but if unofficial reports may be trusted, both road and engine have proved already very costly to keep in order. It is worthy of remark, though we have no means of testing the absolute truth of the statement, that about the time when the above-mentioned feat of speed was accomplished it was proposed to be turning out from the establishment of Messrs. Sharp and Roberts, eminent engine-builders of Manchester, of a narrow-gauge engine called the Atalia, which, after being tested on the Birmingham line, was not found capable of maintaining a speed of 58 miles an hour with a train of ten cars, over undulating gradients, and which, with its tender, weighed only 25 tons. Allowing that this engine was largely used for trial, and in the case of pausing before the astonishing speed of the 'Great Western' engine is set down to the credit of the broad gauge. The revival, by Mr. Fairley, within the last few months, of the often attempted road of the London and Brighton railway, which has in locomotive power in locomotive engines, perhaps only deserves notice here to call attention to the fact that, supposing the mechanical difficulties to be overcome, which, from the action of Mr. Fairley, have already been increased, power, or the case, it remains a question whether the power required for the condensation of air into the reservoirs from which the proposed locomotives were to be supplied, might not be as well or better employed in propelling the trains in some other way; and to remark, that many of the assertions made respecting the superiority of the proposed air-locomotives to steam-engines in locomotive and tractive power, are too absurd for serious refutation. Atmospheric Railway System. To what has been already said on this subject under RAILWAY, P. C., p. 280, and Atmospheric Railway System, a paragraph, 'that there may be added. Of the proposed atmospheric line alongside of the London and Croydon railway, alluded to in the last-mentioned article, a portion of about 5 miles, between Croydon and the edge of the forest, the danger of fire, and the number of the running of experimental trains, and has been employed for working the regular traffic, in conjunction with locomotive engines from London to Forest Hill, for several months. This railway is constructed upon the eastern side of the locomotive line, and therefore, to avoid interference with the Brighton line at the point where it diverges from the Croydon, it is conducted over that railway by a timber viaduct, to which it rises on each side by a slope of 1 in 50. The first experiments were highly satisfactory, a speed of from 60 to 75 miles per hour, with considerable loads, having been attained, and the formidable slopes of 1 in 50 ascended without difficulty, especially in the summer, when too many is usually being brought to a stand at its foot. It was also found, by stopping the action of the stationary engine near the middle of the 5-mile length, and leaving the whole 5 miles to be worked by the atmospheric system, that a considerable saving in time was thereby made, as all the necessary construction of the air-pumps, or some other matter capable of easy remedy, than with the system of propulsion itself. In several instances a greater has, from some cause or other, been observed, especially at the inclined planes of 1 in 50 above referred to; and during the very hot summer of 1846 an unexpected difficulty arose from the iron tubes becoming so heated as to melt the composition by which the valve is sealed;
by the failure of which the vacuum was destroyed, and it
became necessary again to transfer the traffic to the locomotive
line until a harder composition of a new and, it is
anticipated, a better valve lived. In the mean time
the continuation of the atmospheric line from Forest Hill to
New Cross has been nearly completed, and arrangements
have been made for its opening; but however the Croydon and
Epsom line has been constructed, and is expected to be ready for traffic about Christmas, 1846, the
atmospheric system has not been laid upon it, and it is
intended to work it in the first instance with locomotive power;
the engineer-in-chief, Mr. William Cubitt, having recom-
manded that course on the ground that the atmospheric sys-
tem is the one that has been most exposed to test and
comparison, is 'too important a matter either to be hastily extended or
hastily thrown aside.' In the session of 1846 the act for the
projected Direct London and Portsmouth railway (which was
defferred from the session of 1845 for want of time to pass
through the House of Lords) was passed; but the arrange-
ments which have been entered into between its promoters and
the London and Brighton and London and South-Western
railway companies render it almost certain that it will be
constructed as a locomotive line. Under these circumstances,
which render the anticipated extension of the atmospheric
system for the present doubtful, it is unnecessary to enter
upon a consideration of the part of the issues suggested by a
comparison between it and the locomotive system; or to notice
the arguments which have been adduced in favour of atmos-
pheric traction on the ground of its superior safety, economy,
and power, in which the locomotive engines are unsuitable. To what has been
said under ATMOSPHERIC RAILWAY on the history of
schemes for atmospheric propulsion we may add that since
that article was written, many new contrivances have been
propounded, of which perhaps the most deserving of notice
is that of the late M. Hallette, in which the connection between
the cargages and the piston is effected by a thin flat bar or
rods, passing through a circular opening at the side of the
atmospheric tube, which slit is closed during the passage of the
coupler by the contact of two continuous air-bags, or air-tight and highly elastic hose or pipes of
caoutchouc covered with cotton and leather, which are
inserted, in a collapsed state, in grooves or cavities formed
on the top of the pipe to receive them, and are then inflated
with air so as to press against one another with considerable force.
The action of this, the most simple of all the proposed valves,
is illustrated by the passing of a paper-knife between the
closed lips; the valve itself consisting, as it were, of a pair of
continuous lips, capable of being pressed together with any
required force by inflating with compressed air. Many of the
other proposed plans are more remarkable for their compli-
cation than anything else. We may refer to the 'Mechanics'
Magazine' for January 24, 1846, for a list of one or
which will be found published in the Technical Journal;
many of these, although we need further information in order to judge of its practical value. The in-
vention to which we allude is the magnetico-atmospheric rail-
way of the Patent of railway engines which will be necessary for a valve is avoided by the employment of electro-
static force to connect the cargages with the piston in the tube.
From a letter in the following number of the magazine
it would appear that the patents are not alone in their claim
to this ingenious idea.

Railway Labourers and Railway Accidents. The condi-
tion of the labourers employed on railways, the state of wretched-
liness and demoralization in which they are often compelled
to live, and the loss of life, injuries of person, and deterior-
tion of health, to which they are subjected by the careless
management of contractors, have become matters of anxious investigation to all who are interested in the welfare of the
labouring classes. 'A Report of the Select Committee of the
House of Commons, appointed to inquire into the Condition
of the Labourers employed in the construction of Railways and
Canals, and the state in which they are employed,' was laid before
the House of Commons and printed with supplementary
Observations; being a Letter of John Robertson, Esq., Sur-
geon, President of the Society. 'Statements on Railway

Contracts and Railway Labourers, by Robert Rawlins,
Esq., Engineer of the Bridgewater Trust.' 'Observations as to
some of the Effects produced in this country by the
expenditure of Capital on Labour in the construction of Rail-
ways; together with Observations on the Principles of Legis-
lation and Jurisprudence applicable to the Public Protection,
by Prevention of Factories Acts, and for the better Regulation
of Labourers employed in dangerous works; by Edwin Chad-
wick, Esq., Barrister-at-Law,' &c.

It is abundantly proved by the evidence adduced in these
papers, that large bodies of workmen are hastily collected,
and crowded into hovels, without any provision being made for
comfort or decency; that they are not only hard worked, but
exposed to the necessary risk of life and limb; that they are cheated of a considerable part of their
hard-earned wages, by being compelled to deal at tally-shops
by means of tickets, while payments are only made once a
month or even two months, thus, by a system of work and
payment, to expose the men to the temptation of spending carelessly, and
of drunkenness, by receiving the balances due to them in an
accumulated sum; that no provision is made for instruction,
religious or merely educational, for the men or their children,
and that there is, in consequence of all this want of care and
want of principle on the part of the contractors, great wretched-
ness, discontent, disorder, drunkenness, and debauchery, on the
part of the labourers. The Directors of the Liverpool and
Bury Railways are stated to have voted 1000l. a year for the
special purpose of the care of the workmen, to obtain good
lodgings and rooms for living in, and other comforts and
conveniences.

As many millions of pounds must be spent, and many thou-
sands of men be employed in the construction of the railways
which have already received the sanction of Parliament, it is
desirable that the Legislature should interfere to protect the
labourers, by suitable legislative measures, from the neglect
and cruelty of those who employ them.

With respect to accidents which occasion loss of life or in-
jury of limb, either to workmen in the construction of railways,
or to passengers in transit, Mr. Chadwick was examined by the
Committee of the House of Commons before mentioned
as to the provisions of the French law in such cases. Mr.
Chadwick adduced the following provisions of the 'Code
Civil':—

'Art. 1383. Every act whatsoever of the man who occa-
sions a damage to another, obliges him by whose fault it hap-
pens to repair it.'

'Art. 1383. Every one is responsible for the damage he
has caused, not only by his act, but by his negligence or by his
imprudence.'

'Art. 1394. A man is responsible only not for the
damage occasioned by his own act, but also for that which is
occasioned by the act of persons for whom he should answer,
or of things which he keeps in his charge.'

These provisions of the French law, Mr. Chadwick states,
were understood to extend to companies, as well as to indi-
viduals; yet, by a law of July 15, 1843, on the general ma-
terial law of railways, which made the directors responsible for
the greater safety of railway passengers. The 22d clause
makes all owners or lessees of railroads responsible to individuals and
the state, for injury caused by managers, directors, or
any people employed in any capacity whatever in the working
of them. Other clauses, from 16 to 21, enact penalties
against those through whom accidents may be brought about,
and for the mere violation of the regulations established by
the king or prefects for the management of railways, even
when no accident resulted therefrom.

British Railways.

In the following tabular view of railway acts passed since
1840, supplementary to that given in P. C., p. 261, a large propor-
tion of those described as for new lines are merely for
constructing branches from or extensions of lines previously
authorized; while the remainder may be calculated to lessen the peculiar evils, if any, of that condi-
tion,' has been published (1846). The Statistical Society
of Manchester have also published (1846) the following Papers,
which must be taken only as a part of the papers which
have been published. 'Statistical View of the Accidents,
Fatal Accidents, Wounds, and Injuries, sustained by Work-
men engaged in the construction of the Summit Level Tunnel
of the Sheffield and Manchester Railway; and a Description
of the ground, with the results of the observations of
Observations; being a Letter of John Robertson, Esq., Sur-
geon, President of the Society. 'Statements on Railway
### Railway of England and Wales.

**Aberdare.**—From the Talyllyn Railway, near Ynys Mynegick, to Aberdare; length, with a branch, 84 m.; act passed 1843; opened August, 1846.

**Aberdare and Beaconsfield, and Boston and Eastern Junction.**—From the Ambergate station of the Midland Railway, through Nottingham, to Spalding and Boston, with branches. Main line to Spalding, exclusive of portions of lines to Lincoln and Licoln lines which are to be used, 594 m.; Boston extension 194 m.; Seafor branch 9 m.; canal branch 1 m.; Boston branch 2 m. Act passed 1843; sold to the Great Northern Railway Company. The act confers powers to purchase the Nottingham and Grantham canals.

**Ashby, Newton, and South Devon.**—A branch from the South Devon Railway, near Newton Abbott; length 104 m.; act passed 1846. The South Devon Company has an interest in this line.

**Ashfield and Hasland.**—See Brighton, Lewes, and Hastings; Rye and Ashford Extension.

**Ashford Branches.**—See Manchester and Birmingham, and Sheffield, Ashton-under-Lyne, and Manchester.

**Ashton, Stalybridge, and Liverpool Junction.**—Sold to the Manchester and Leeds Railway Company, from whose line it branchet off. Length of line from junction to Manchester 116 m.; and to Stalybridge in September, 1846. An act of 1845 authorizes a branch of 1 m. to join the Manchester and Birmingham line in Ashfield and Hasland. Act passed 1846.

**Aston and Gloucestershire.** [P. C., p. 262.]

**Aylesbury [P. C., p. 262.**]—Sold to the London and Birmingham, now London and North-Western Railway Company, whose line it joins at Bletchley. Length 16 m.; act passed 1845; opened November, 1846.

**Berks and Hants.*—A broad gauge line from the Great Western Railway at Reading to Newbury and Hungerford, 254 m., with a branch of 134 m. to join the London and South-Western Railway at Basingstoke. Total length 39 m.; act passed 1845; sold to the Great Western Railway Company.

**Birkenhead, Lancashire, and Cheshire Junction.**—From the Chester and Birkenhead Railway at Birkenhead to the London and Birmingham Railway at Stockport, 384 m., with branches amounting to 79 m.; total length 46 m.; act passed 1846. The company has agreed to amalgamate with the Chester and Birkenhead railways.

**Birmingham, Bristol, and Thames Junction.**—See West London, Birmingham, and Derby Junction [P. C., p. 262.]

**Birmingham and Midland Railway.**—Branch of the London and Birmingham Railway at Stockport, 384 m., with branches amounting to 79 m.; total length 46 m.; act passed 1846. The company has agreed to amalgamate with the Chester and Birkenhead railways.

**Birmingham, Bristol and Gloucester.** [P. C., p. 262.**]—Main line, from the London and Birmingham Railway, at Birmingham, to Gloucester, 33 m.; from the Westbury 2 m.; from the Gloucester Canal at Gloucester 1 m.; completed 1841. Amalgamated with the Bristol and Gloucester Railway, and the united lines leased in competition with the Midland Railway Company. The company has also authorised extensions at both ends of the line, and a branch at Stoke Prior, amounting together to 11 m.; and in 1846 the
Midland Company acted for a branch from King's Norton to Hales Owen, length 5½ m.; and to Some, Middlewich, and Manchester.—From the Grand Junction Railway at Aston, near Birmingham, to the Trent Valley Railway at Lichfield; length 14½ m.; act passed 1846.

Birmingham and Oxford Junction.—Main line from Birmingham to the Oxford and Rugby and Oxford, Worcester, and Wolverhampton (broad gauge) line at Wolverhampton, 11½ m.; branch to Dudley, 2½ m.; total length 14½ m.; act passed 1846. This undertaking was projected to connect the London and Birmingham Railway with the Wolverhampton and Dudley line. As this was never carried out, however, both this line and the Birmingham, Wolverhampton, and Dudley, with which it is intended to amalgamate, must be laid upon the Birmingham and Oxford Junction line.

Birmingham and North Midland.—From the Oxford and Rugby and Oxford, Worcester, and Wolverhampton (broad gauge) line at Wolverhampton, 11½ m.; branch to Dudley, 2½ m.; total length 14½ m.; act passed 1846. This line was never built, and the powers to adopt the broad gauge were not exercised. See page 672 for more details.

Bridgwater Navigation and Railway.—A short line of 2 m. to connect the Bridgwater and Bridgewater with the Bristol and Exeter Railway; act passed 1845.

Bristol and Torrington Canal, Railway, and Harbour.—The act for this line, a branch 10½ m. in length from near Stolford to Torrington, was passed in 1845, to connect the Bristol and Exeter Canal Company with the Bristol Channel at or near Stolford, about 9 m., with three tunnels and two bridges. The line was completed in 1850 but was never worked, as it was never completed to a harbour at Stolford. This and the Chard Canal Railway are intended to form portions of a projected line to connect the Bristol and Exeter Railway with the Western Counties Railway.

Bridgwater Branches.—See Hull and Salisbury, and York and North Midland.

Bristol and Chichester.—An extension of the Sambrean Branch of the London and Brighton Railway, by Worthing, and between Littlehampton and Arundel, to Chichester.

Brighton and Hove.—A new line of 3½ m. to Hove, with a branch to Brighton Marina, 2½ m.; act passed 1845, and opened in 1846.

Brighton, Lewes, and Hastings.—The original act, passed in 1844, was for a line from the Ouse to Hastings; an extension, 6½ m., from the Ouse to the River Uck, was granted in 1845. Shortly after, a branch of 9½ m. from Lewes to the London and Brighton Railway at Keymer, to shorten the distance to London, was added, and under that for the line next following in this table the original line was diverted from the Hastings end. The main line was opened in June, 1846, from Brighton to Bulverhythe, 5½ m.; from Brighton and about 2½ m. from Hastings, whence an extension to the permanent station at St. Leonards began and was opened in November, 1846. An act of 1846 sanctioned some deviations from the Kemyer branch, and branches to Eastbourne, nearly 4½ m.; to Hallisham, nearly 3 m.; and to Seaford and Newhaven (the new branch of the London and Brighton Company not having been made) 8½ m.; total, 16½ m. Sold in 1848 to the London and Brighton, now the London, Brighton, and South Coast Railway Company, by whom the above branches are to be made.

Brighton, Ewell, and Esher.—A line of 11½ m. to Ewell, and an extension of the Epsom and Ashtford branch; act passed 1845, and opened in 1846.

Bristol and Exeter.—Formed by the amalgamation of the Bristol and Gloucester and Birmingham and Gloucester lines, which, immediately after agreement, is to be known as the Great Western Railway Company. Their consolidation with one another and with the Midland is sanctioned by an act of 1846.

Bristol and Gloucester.—An act of 1845 sanctioned a new branch of 4½ m. at Bristol, one of 2½ m. to Clevedon, one of 20½ m. to Yeovil, and one of 4½ m. to Taunton. Total length 31½ m.; act passed in June, 1846; and a third act was obtained in 1846, for a branch of about 15½ m. to the North Union line at Bamber Bridge, to thence to Preston, for 9½ m.; act passed in 1846. A branch from Blackpool, making altogether about 2½ m. Another act of the same session confirms the amalgamation of the whole undertaking with the East Lancashire Railway.

Buckingham and Breckley.—See Buckinghamshire.

Buckinghamshire.—This undertaking consists of two distinct lines, sanctioned by separate acts of 1845: one from the Oxford and Bletchley Junction, from Oxford to the London and Birmingham Railway at Bletchley, length 29½ m.; and the other, from the Midland Railway to the first-mentioned line to Buckingham and Breckley, about 10½ m.; total length, 40 m. The acts confer power to sell or lease the lines to the London and Birmingham, now London and North Western Railway Company.

Bulloch.—See Forest of Dean.
Dundee and London and Birmingham. — From the London and Birmingham line near Leighton Buzzard; length 2 m.; act passed 1845. To be leased or sold to the London and North Western Railway Company.

Dorset Central, New Forest, and Roan, 263. — Length, from the Seasham Railway to the Stanhope and Tyne Railway (both of which were made without acts of parliament), nearly 5 m. Purchased by the Newcastle and Darlington Junction Railway Company.

Durham and Sunderland [P. C., p. 263].—Purchased by the Newcastle and Darlington Junction Railway Company, and to be adapted to the steam-engine system.

East and West India Docks and Birmingham Junction. — From the East and West India Docks to the London and Birmingham line near Newhall; length 2 m.; act passed 1846. Promoted by the London and Birmingham Railway Company.

East and West Yorkshire Junction. — From Knarborough to the Great North of England Railway about 14 m. from York; length, barely 15 m.; act passed 1846.

East Anglia. — Under this title it is proposed to amalgamate the Lynn and Ely, Lynn and Dereham, and Ely and Huntingdon lines, and to lease them to the Eastern Counties Railway Company.

East Lancashire (originally Manchester, Bury, and Ramsden). — From the Manchester, Salford, and Eccles Railway about 4 m. from Manchester, by Bury, to Rawtenstall; length 14 m.; original act passed 1844; amendment act, in which the Company was altered, 1845; act passed September, 1845. The branches have been amalgamated with the Blackburn, Burnley, Accrington, and Colne, the Blackburn and Preston, and the Liverpool, Manchester, and Southport, and the branches of the railway have been abandoned. The track between the line and the Manchester, Salford, and Eccles Railway have been added to the stock of the Company. Act passed 1846. Length 27 m.; act passed 1846; and deviations to the extent of 83 m. on the extension line.

East Kent Railway. — From Great Chart to Tenterden and Aford, to Bordon; length 48 m.; act passed 1846. Sold to the Great Northern Railway Company.

East Riding of Yorkshire. — From Driffield and Yarmouth, 253. — Opened from London to Colchester, 151 3/4 m., in March, 1843, and the remainder of the original parliamentary line abandoned; the Eastern Union; Ipswich, Bury, and Newmarket, 301 3/4 m.; act passed 1845. The extension of about 30 miles from Newmarket to Ipswich is taking up place. In 1843 the Eastern Counties Company made terms of amalgamation with the Northern and Eastern Company, and became possessed of the possession of the line of about 30 miles from Newmarket to Ipswich, and of the branch of Great Yarmouth. In 1844 the Eastern Counties Company obtained an act for extending this northern line by Cambridge to Ely, and thence eastward to Brandon, and westward to Peterborough, making altogether 72 m. of new line, of which the portion from Bishop's Stortford to Cambridge, Ely, and Brandon, was completed in July, 1845. The course of the Ely and Peterborough line was altered for a length of 298 m. under an act of 1845, in order to pass through Marcham and Newmarket, November (1845) nearly completed. Another act of the same session authorised a line of 1 1/3 m. from Cambridge to Huntingdon. In 1846 the Eastern Counties Company abandoned the connection of their line with the London and Stratford stations; making a line from 11ford to Epping, 10 1/3 m.; and two branches, amounting together to little more than 10 m., which were abandoned. The line remains, which, as well as the North Woolwich, they have purchased. See also East Anglian; Enfield and Edmonton; London and Blackwall Extension Line; Stratford, Upnor, Woolwich, West Ham, Newmarket and Chesterton; and Wissich, St. Ives, and Cambridge Junction. The gauge of the Colchester and Northern and Eastern lines was altered in 1844.

Eastern Counties and Thames Junction. — From Stratford to the mouth of the river Lea; length 24 m.; act passed 1844; opened April, 1846. Sold to the Eastern Counties, which see. See also North Woolwich.

Eastern Union. — From Colchester to Ipswich; length 17 m.; act passed 1844; opened June, 1846. From Colchester the line was made by the Eastern Counties Company, the land being theirs; but this portion has been sold to the Eastern Union Company. The eastern end of the Colchester, Stour Valley, Southwold, and Huntingdon Eastern Union and Hadleigh Junction line, and Ipswich and Bury St. Edmunds.

Eastern Union and Hadleigh Junction. — Length, with two junctions with the Eastern Union line, 64 m.; act passed 1845. Sold to the Eastern Union Railway Company.

Ely and Huntingdon. — Length, under original act of 1845, 22 m.; but subsequently shortened by an arrangement for using the Eastern Counties line about 1 m. from Ely. See Ely Anglian.

Enfield and Edmonton. — From the Northern and Eastern Railway at Edmonton; length, 3 m.; act passed 1846. Power given to sell the line to the Eastern Counties Company.

Epping. — See London and Blackwall Extension; and Eastern Counties.

Essex Valley. — From the Midland Railway at Sawley to the Mansfield, Heanor, and Matlock Railway; length, 18 1/4 m.; act passed 1845; sold to the Midland Railway Company. For extension and branches see Midland.

Essex and Hertford. — Length of 18 1/4 m.; act passed 1845. Laid
to the Bristol and Exeter. To open December, 1846. An act for a similar line was passed in 1843, but was not carried into effect.

Fernier and Exmouth.—Length, with a very short branch at Topsham, 10 m.; act passed 1846.

Fleetwood, Preston, and West Riding Junction.—From Preston to Clitheroe: length, nearly 16 m.; act passed 1846. See Preston and Clitheroe.

Forest of Dean (formerly Bollero Hill).—[P. C., p. 263.]

Ferrers.—Original line, under an act of 1844, intended to connect near Dalton, Lindsey, and Slate-Quarries at Kirtlington, with the coast at Barrow and Ramsgate; length, 104 m. Opened in June, 1846, and passenger-traffic worked in connection with steamers from Fiel harbour to Fleetwood. An act of 1846 authorized extension of 34 m. from Sandal to Burton, one of 4 m. from Dalton to Ulverstone, and branches to the Whittriggs and Butts iron-mines, making a total of 9 m.

Gloucester and Cheltenham.—[P. C., p. 263.]

Gloucester and Dean Forest.—From Gloucester to the Monmouth and Hereford Railway, and to the South Wales Railway at Monmouth. Act passed 1846. To be laid on the broad gauge, and leased or sold to the Great Western Railway Company.

Great Eastern Railway (London and) E. Bay.—[P. C., p. 223.].—Opened February, 1842. See Great Eastern Railway.

Great Northern Railway.—[P. C., p. 263.], excepting the branch to the Great Northern Union station (linking the Great Northern Railway and the West Riding Railway Company), which was opened in 1845. The line extends from the Great Northern Union station to the Grand Junction Railway at London, and to the Hull, Beverley, and York Railway at York. The branch to the Great Northern Union station was opened in 1846. See Great Northern Railway.

Great Western (P. C., p. 263.)—Complete June, 1841. The company have purchased the Berks and Hunts, the Cheltenham and Great Western Railway, the Cheltenham and Exeter, and the Oxford and Rugby lines; lease the Bristol and Exeter: and posses the Oxford Branch, which see. See also, for further connections, the Birmingham and Oxford, and the Birmingham, Wolverhampton, and Dudley; Bristol and South Wiltshire, and Dean Forest; Great Western and Uxbridge; Great Western and Wymond; Oxford, Worcester, and Wolverhampton; Burnley; West Yorks; and Wilt, Someret, and Weymouth.

Great Western and Uxbridge.—Juts the Great Western line at West Drayton; length rather over 24 m.; act passed 1846. To be sold to the Great Western Railway Company.

Great Western and Wymond.—From the Great Western line at Maidenhead to Wymond. Act passed 1846. To be sold to the Great Western Railway Company.

Greenwich and Gravesend.—See South-Eastern Company.

Guildford Extension, Portsmouth, and Fareham.—Projected as the Guildford, Chichester, Portsmouth, and Fareham Railway; but the greater part of the line was authorized by the Direct London and Portsmouth, the act, passed in 1846, sanctioned only a line of about 4 m. from Guildford to the Direct London and Portsmouth at Farnham. The branch at Sandown, near Weymouth, is to be built with Portsmouth. The power to make these has been sold to the London and South-Western Railway Company.

Guildford Junction and London and South-Western Railway: length 6 m.; act passed 1844; opened May, 1845. Sold to the London and South-Western Railway Company. See Guildford East Junction and Nonsucham, and Guildford Junction line (which see), to the Newcastle and Dartington Junction, now York and Newcastle Railway Company.

Hay.—[P. C., p. 263.]

Hove.—[P. C., p. 263.]

Hoy.—[P. C., p. 263.].—Adapted to passenger traffic in 1843. See West Cornwall.

Hucknall and Westbridge.—[P. C., p. 263.]

Hunsford and Wandle.—[P. C., p. 263.]

Hull and Selby.—[P. C., p. 263.].—An act of 1845 sanctioned a branch of 31 m. from Hull to Bridlington, the greater part of which was opened in October, 1846, another point of which authorizes the leasing or sale of the whole undertaking to the York and North Midland and Manchester and Leeds Railway Companies. See Ipswich and bury, and Norwich. See Ipswich and bury, and Norwich. See Ipswich and bury, and Norwich.

Hull and Selby.—[P. C., p. 263.].—An act of 1845 sanctioned a branch of 31 m. from Hull to Bridlington, the greater part of which was opened in October, 1846, another point of which authorizes the leasing or sale of the whole undertaking to the York and North Midland and Manchester and Leeds Railway Companies. See Ipswich and bury, and Norwich. See Ipswich and bury, and Norwich.

Hull and Selby.—[P. C., p. 263.].—An act of 1845 sanctioned a branch of 31 m. from Hull to Bridlington, the greater part of which was opened in October, 1846, another point of which authorizes the leasing or sale of the whole undertaking to the York and North Midland and Manchester and Leeds Railway Companies. See Ipswich and bury, and Norwich. See Ipswich and bury, and Norwich.

Hull and Selby.—[P. C., p. 263.].—An act of 1845 sanctioned a branch of 31 m. from Hull to Bridlington, the greater part of which was opened in October, 1846, another point of which authorizes the leasing or sale of the whole undertaking to the York and North Midland and Manchester and Leeds Railway Companies. See Ipswich and bury, and Norwich. See Ipswich and bury, and Norwich.

Hull and Selby.—[P. C., p. 263.].—An act of 1845 sanctioned a branch of 31 m. from Hull to Bridlington, the greater part of which was opened in October, 1846, another point of which authorizes the leasing or sale of the whole undertaking to the York and North Midland and Manchester and Leeds Railway Companies. See Ipswich and bury, and Norwich. See Ipswich and bury, and Norwich.

Hull and Selby.—[P. C., p. 263.].—An act of 1845 sanctioned a branch of 31 m. from Hull to Bridlington, the greater part of which was opened in October, 1846, another point of which authorizes the leasing or sale of the whole undertaking to the York and North Midland and Manchester and Leeds Railway Companies. See Ipswich and bury, and Norwich. See Ipswich and bury, and Norwich.

Hull and Selby.—[P. C., p. 263.].—An act of 1845 sanctioned a branch of 31 m. from Hull to Bridlington, the greater part of which was opened in October, 1846, another point of which authorizes the leasing or sale of the whole undertaking to the York and North Midland and Manchester and Leeds Railway Companies. See Ipswich and bury, and Norwich. See Ipswich and bury, and Norwich.
Launceston and Victoria [P. C., p. 263].—Abandoned.

Leeds and Bradford. — Original line, under an act of 1844, from Leeds, along the valley of the Aire, and by Shipley, to Bradford, 155 m., with a branch of 14 m. to the North Midland Railway, opened in July, 1846. An act of 1845 authorises an extension from Shipley to Colne, with a branch to Halton, together 30 m.; and acts of 1846 provide for an alteration of the route of 1 m., and a line to the West Riding Union Railway, at Bradford. After agreeing to amalgamate with the Manchester and Leeds, an arrangement was made in 1846, to supersede it by a perpetual lease of the whole undertaking to the Midland Railway Company.

Leeds, Dewsbury, and Manchester Junction. — From the Leeds and Bradford line, near Leeds, to the Dewsbury and Leeds Railway at Kirkstall, and thence to Huddersfield, being a main line of 31 m., with branches amounting to 4 m. The line from Kirkstall to Huddersfield, however, is only to be made if the Huddersfield and Manchester Company fail to complete theirs. Act passed 1845. A second act of 1846 provides for deviations at Dewsbury, and an extension of the main line at Huddersfield, to form a branch of 6 m. to the Birrastle branch, nearly 3 m. To be leased to the London and North-Western Railway Company.

Leeds and Selly [P. C., p. 263].—Purchased by the York and North Midland.

Leeds and Thirsk. — Main line 234 m.; branches to Knaresborough Railway at Wath; a branch of 4 m. to the Great North of England Railways, amounting together to 63 m. These are under the original act of 1845; others, passed in 1846, provide for the extension of the line to the Great Northern Railway from Thirsk to the River Nidd; for a line (the only part sanctioned of a proposed line from the Leeds and Thirsk Railway at Wath to Harrogate) from the Great Northern Railway to Harrogate; to the Stockton and Hartlepool Railway at Billingham, near Stockton, nearly 20 m., short branches, amounting to about 14 m. to the Great North of England Railways; and a line for connecting the line of the Great North of England Railways with that of the Cleveland Bridge. This last-mentioned line is called the St. Helen's branch. See also Wathwale.

Leicester [P. C., p. 263].—Acts of 1846 confirm the purchase of this line by the Midland Railway Company, and confer on the purchasers power to alter 14 m. of the line, and to open branches to Loughborough, 10 m.; to Burton-upon-Trent, 14 m.; and to Swadlincote colliery, nearly 25 m.

Lincoln and Corby. — Length, main line, 65 m.; branch to the Cheesewring, 93 m.; act passed 1843; partly opened 1844. For Burton-on-Trent branch, worked by joint stock company.

Cornwall.

Liverpool and Bury. — Original line, under an act of 1845, from Liverpool to Wigan, Bolton, and Bury, 34 m. Acts of 1846 authorise an extension of 3 m. to Tyhe Barn Street, Liverpool; a branch of nearly 1 m. from the New Springs branch to the North Midland Railway; and an amalgamation with the Manchester and Leeds.

Liverpool and Manchester [P. C., p. 263].—The junction line referred to above is connected with the main line of the Liverpool and Manchester Company by a branch completed in May, 1844. An act of 1845 authorises a new entrance into Liverpool, and a branch to join the Manchester, Bury, and Rossendale line at 50 m. Another act of the same session ratified the amalgamation of the Liverpool and Manchester, with its connections, the Bolton and Leigh and Kenyon, the Great Central Railway, from which it is said to be merged in the London and North-Western.

Liverpool, Manchester, and Newcastle-upon-Tyne Junction. — Main line, from the Leeds and Bradford Railway at Eaket, to the Richmond branch of the Great North of England Railway at Scoiton, 474 m.; branch to Hawes, over 9 m.; act passed 1846. This undertaking comprises the main line of the Leicestershire and North Yorkshire Railway, and, in the Hawes branch, a portion of that projected by the Liverpool, Manchester, and Newcastle sponson, the two lines having been consolidated while before parliament. The Hawes branch, being identified with part of the York and Glasgow Union projected line, is not to be made if that line be, as intended, constructed by the Northern Counties Union Railway Company, which see. The capital is partly subscribed by the Manchester and Leeds Railway Company.

Liverpool, Ormskirk, and Preston. — Main line, from the Liverpool and Bury Railway at Walton-on-the-Hill to the North Union Railway at Penwortham, 234 m.; branch to the Blackburn and Preston Railway, nearly 24 m.; branch to Blague-Gate Collieries, 3 m.; branch to the junction of Walter Street and Regent Street Junction, Part of the total 29 m. Amalgamated with the East Lancashire Railway.

Ludlow [P. C., p. 264].—The total length of this line and its branches is 8 m. for evidence before the Gauge Commissioners (Q. 6041), is 45 m.

Luce and the Vale. — From London to Margam; length 15 m.; act passed 1846. As it joins the South Wales Railway, this line is to be laid on the broad gauge. The company has amalgamated with the Duffryn-Llwyd and West-Gower Railway Company.

London and Birmingham. — First act of 1843 this company has made a branch of 474 m. from Bishworth, by Northampton, to Peterborough, which was opened in June, 1845. It was not until 1846 that the London and Birmingham Railway Company started the numbering of these companies, under the comprehensive title of the London and North-Western Railway Company. Acts of 1846, for the extension of nearly 1 m. at Birmingham, to near Navigation Street; a branch of 104 m. to the London and Birmingham Company near Coventry, to the Trent Valley Railway at Nuneaton; an extension of 1 m. at Leamington; and a line of nearly 6 m. from their main line at Wedon to the Northampton and Pecknall line at Northampton, and to enlarge their stations at London, Rugby, and Coventry. For other connections and arrangements (enumerated here, rather than under the title of London and North-Western, because they have for the most part been made by the London and Birmingham Railway Company, and are under separate acts) see Bedford and London and Birmingham; Birmingham, Leicestershire, and Manchester; Birmingham, Wolverhampton, and Stafforshire; Nottingham, Lincolnshire; Coventry; Leamington; Birmingham, Leicester; Stratford and Birmingham; Shrewsbury and Birmingham; Shrewsbury and Hereford; Shropshire Union; etc.

London and Blackwall (formerly Commercial) [P. C., p. 264].—Extension line of 3 m. to near Fenchurch Street opened 1843. In August, 1844, the London and Blackwall extension, from Stepney to Fenchurch Street, to accommodate the traffic expected from the Eastern Counties Railway by the London and Blackwall East Junction Railway, was purchased by the London and Blackwall Company. The East and West India Dock and Birmingham Junction line will join the London and Blackwall Railway, and the eastern junction line of 15 m. between the London and Blackwall Railway at Stepney and the Eastern Counties Railway at Bow. Act passed 1845, since which the line has been sold to the London and Blackwall Railway Company, which see.

London and Brighton [P. C., p. 264].—The main line, of 414 m., from near Croydon to Brighton, was completed in September, 1841; the Shoreham branch, of 24 m., in May, 1845. The other branches mentioned in P. C. were abandoned, but are replaced by branches granted in 1846 in connection with the Brighton, Lewes, and Hastings line. The 12 m. between the Croydon Railway and Reigate or Redhill, is worked over by the Brighton and South Coast Railway; the companies joint, and at its cost having been repaid by the South-Eastern Company, which see, to maintain the southern half of that portion of the line. The London and Brighton and Buxton Railway Company have purchased the Brighton and Chichester Railway, with its Portland and Lewes and Hastings, Brighton, Lewes, and Hastings Railway, which see for new branches authorised in connection with them. In 1845 they obtained an extension of 23 m. to Shoreham, and another of 4 m., partly following the course of the abandoned Shoreham Iron Railway, from Croydon to the London and South-Western Railway at Wandsworth, and for confirming an amalgamation with the London and Croyden see.

London, Brighton, and South Coast. — This is the new name of the London and Brighton Railway Company, with its branches to Hastings, Chichester, and Portsmouth, as above mentioned, conferred by the act—which amalgamates it with the London and Croyden.

London and Croyden [P. C., p. 264].—The Company have purchased the Croydon and Epsom Railway (which see), and Acts of 1846 authorise the construction of the Croydon and Epsom Railway. The line is to run from its main line to Epsom, and in 1846 they obtained another for a branch of 69 m. from the main line to East Grinstead, and a branch or extension of 64 m., partly following the course of the abandoned Shoreham Iron Railway, from Croydon to the London and South-Western Railway at Wandsworth, and for confirming an amalgamation with the London and Croyden see.
Greenwich Railway to Gravesend. The London Bridge station was opened by the London, Greenwich, and South-Eastern Railway Companies.

**London and North-Western.** Under this new title, by an act of 1846, the line is extended from the Manchester and Liverpool Railway to Hazel Grove via Stockport, and a branch to Congleton, with an extension to Macclesfield, via Sandbach and Northwich, to the Manchester and Liverpool Railway, at Crewe, which was completed and opened in 1847.

**Manchester, Ashton-under-Lyne, and Manchester Railway.** By an act of 1846, the company is formed to construct a line from Manchester to Ashton-under-Lyne, with a branch to Stockport, and a junction with the Manchester and Liverpool Railway at Stockport. The line was opened in 1848.

**Manchester and Bolton.** By an act of 1846, the Manchester and Bolton Railway Company was formed to construct a line from Manchester to Bolton, with a branch to Rivington and Hindley.

**Manchester and Leeds.** By an act of 1846, the Manchester and Leeds Railway Company was formed to construct a line from Manchester to Leeds, with branches toBradford and Halifax.

**Manchester and Liverpool.** By an act of 1846, the Manchester and Liverpool Railway Company was formed to construct a line from Manchester to Liverpool, with branches to Warrington and Northwich.

**Manchester and Stockport.** By an act of 1846, the Manchester and Stockport Railway Company was formed to construct a line from Manchester to Stockport, with a branch to Stockport and Macclesfield.

**Manchester and Warrington.** By an act of 1846, the Manchester and Warrington Railway Company was formed to construct a line from Manchester to Warrington, with branches to Lyme and Northwich.

**Manchester and Wigan.** By an act of 1846, the Manchester and Wigan Railway Company was formed to construct a line from Manchester to Wigan, with branches to Leigh and WN. The line was opened in 1846.

**Manchester and Whitchurch.** By an act of 1846, the Manchester and Whitchurch Railway Company was formed to construct a line from Manchester to Whitchurch, with branches to Macclesfield and Congleton.

**Manchester, Ashton-under-Lyne, and Manchester Railway.** By an act of 1846, the company is formed to construct a line from Manchester to Ashton-under-Lyne, with a branch to Stockport, and a junction with the Manchester and Liverpool Railway at Stockport. The line was opened in 1848.

**Manchester and Southport.** By an act of 1846, the Manchester and Southport Railway Company was formed to construct a line from Manchester to Southport, with a branch to Lytham.

**Manchester and Stockport.** By an act of 1846, the Manchester and Stockport Railway Company was formed to construct a line from Manchester to Stockport, with a branch to Stockport and Macclesfield.

**Manchester and Warrington.** By an act of 1846, the Manchester and Warrington Railway Company was formed to construct a line from Manchester to Warrington, with branches to Lyme and Northwich.

**Manchester and Wigan.** By an act of 1846, the Manchester and Wigan Railway Company was formed to construct a line from Manchester to Wigan, with branches to Leigh and WN. The line was opened in 1846.

**Manchester and Whitchurch.** By an act of 1846, the Manchester and Whitchurch Railway Company was formed to construct a line from Manchester to Whitchurch, with branches to Macclesfield and Congleton.
TRA

nearby 1 4 m. to the proposed Nottingham and Mansfield line, making the total length of the line 34 8 m. in all. The line makes several short branches, amounting to about 24 m. 3 from the Erewash Valley Railway, which they have purchased; to make a line, called the Erewash Valley Railway to connect the several branches elsewhere described in connection with it; to make a railway of 162 m. from Nottingham to Mansfield; and to purchase and close the Oakham Canal, which branches of which will be diverted by the Syon and Peterborough line. In addition to the above lines the companies have purchased or leased the Britoil and Birmingham, Leeds and Bradford, and Northern Railways, which see. *Midlands Counties [P.C, p. 264.]-Merged in the Midlands Railway, which see.

Monmouth Branch.-See South Wales.

Monmouth and Hereford.-Main line 22 m.; branch to Westbury 10 m.; branch to the Forest of Dean 44 m.; total 264; act passed 1845. Projected as an extension, upon the broad gauge, from the Cheltenham and Great Western line at Standish, but (see South Wales) the works proceeded for the crossing, but have not been sanctioned by Parliament in 1845 or 1846. The line has been purchased by the Great Western Railway Company.

Moseley.-The line, 9 m., in existence since 1846, is made up of m. 3 from Newport and Pontypool. To be made by the Monmouthshire Canal Company; length, 13 m.; act passed 1845. See Monmouthshire.

Newport and Crewe.-See Shropshire Union.

Newport and Chester.-The company incorporated under this title in 1846, which is in friendly relation with the London and North-Western, and may probably be united with it, obtained three miles of the Symonds: respecting, respectively, the Great Western line, of nearly 45 m., from the Macclesfield branch of the Manchester and Birningham line at Macclesfield to the Birmingham and Derby line at Wellington, with the Burton-upon-Trent termination, nearly 4 m., and a branch of 164 m. from Uttoxeter to the Potteries line near Stoke-upon-Trent, making together 248 m.; the Potteries line, of 264 m., from the same point at Macclesfield to the Trent Valley Railway at Colwich, with the Crewe branch, 84 m., the Newcastle-under-Lyme branch, 44 m., and the branch to join the Grand Junction line at Northwich, farther than 84 m., making together about 54 m.; and a line from the Potteries line at Harecastle to the Manchester and Birningham Railway at Sandbach, about 8 m.; making together about 34 m. The company abandoned the line before the latter act. The Company is empowered to purchase the Trent and Mercury Canal.

North Union.-Formed by the consolidation of the Preston and Wigan Branch Railways. The act of 1846 confirms the amalgamation of the Blackburn and Preston with this undertaking; and one of 1846 sanctions an extension of the line from the Wigan Branch to the Grand Junction (now merged in the London and North-Western) and the Manchester and Leeds Railway Companies jointly.

North Wales & Ribble Navigation.-From the North Union Railway to the Victoria Quay, Preston, 4 m.; act passed 1845. To be made by the North Union Railway and Ribble Navigation Company; length, 33 m.; act passed 1845. See Corwen.
T R A

Lines adopted, the course of the latter from Thirsk to Clifton and a portion of the former from Bishop's Auckland to Teesby.
Northern Union.—See Newcastle and Darlington Junction.
Norwich and Brandon.—By the original act of 1843 this was to be a general way; the work was begun in August, 1845, and an act of 1845 the main line was diverted to pass through Thetford, making the length about 40 m. Opened July, 1845. Amalgamation with the Norwich and Brandon Railway, which see. The 1845 act allows a branch of 11 m. from Wymondham to East Dereham. Not on present map.—See Midland.
Nottingham and Mansfield.—See Midland.
Oxford Branch.—See Basinghamshire.
Oxford Branch.—From the Great Western Railway at Didcot to Oxford, 94 m. and opened June, 1844. Made by the Great Western Railway Company. Gauge 7 feet.
Oxford and Rugby.—From the Oxford branch of the Great Western Railway at Oxford to the Birmingham and Midland Railways at Rugby, length 503 m.; act passed 1845. Sold to the Great Western Railway Company, who are constructing it as a broad-gauge line. See Birmingham and Oxford Junction Railway, and also the account of the gauge controversy, p. 665.
Oxford, Worcester, and Widerhampton.—The original act, passed in 1844, was for a main line of 264 m. in extension of the Oxford branch of the Great Western Railway, with the Worcester branch, 14 m.; the Stoke branch, 4 m.; the Stourbridge branch, 1 m.; and the Stratford-upon-Avon branch, 134 m., the whole line making the length of 286 m. in total 1014 m. An act of 1846 provides for some alterations in the line, and a branch of 9 m. to Stratford-upon-Avon, one of 44 m. to Wilmcote, and a connection of 134 m. of new line. The line is being constructed for the broad gauge, and under a guarantee from the Great Western Railway Company, but provision is made in the original act for paying additional rails where the connection with narrow-gauge lines may render it necessary in order to avoid a break of gauge. (See remarks on the gauge question, p. 655.) The company have leased the Stratford and Moreton Railway, and the act of 1846 gives power to purchase the Stratford-upon-Avon and Stourbridge branches, the former of which they will transfer to the Birmingham and Oxford Junction Railway Company.
Oystermouth.—[P. C. p. 264.]
Pondgate and South Shields.—A private company, formed about 1831 or 1832, constructed, without the authority of an act of parliament, an extensive line called the South Shields and Tynemouth Railway, running for about 34 m. from South Shields, through the northern part of the county of Durham, to Tynemouth, which was worked, at least partially, by locomotive engines, and used principally for coal traffic. It proved an unsuccessful speculation; and in 1842 a new company was incorporated by act of parliament for working a portion of the line, the old company being dissolved. In 1844 the new company, which took the name of the Pondgate and South Shields Railway Company, obtained an act for widening a part of the line from Pondgate Junction to the branch of 4 m. to the Brundling Junction Railway; and under an act of 1846 the whole undertaking has been consolidated with the Newcastle and Darlington Junction, now the York and Newcastle Junction Railway.
Portland.—[P. C. p. 264.]
Poulter Pier and Railway.—The act, passed in 1846, is for widening a pier at Portland, and a railway of nearly 4 m. with a branch of nearly 1 m., to connect it with the Bristol and Exeter line near Bristol, to be laid on the broad gauge, and may be leased to the Great Western or Bristol and Exeter Railway Company.
Portsmouth.—See Brighton and Chichester, Portsmouth Extension; Direct London and Portsmouth; and Guildford Extension, Portsmouth, and Fareham.
Potters Line.—See North Staffordshire.
Preston and Edinburgh.—[P. C. p. 264.]
Preston and Wirral.—[P. C. p. 265.]
Preston and Wyre.—[P. C. p. 265.]
Preston and Wyre.—An act of 1845 authorizes branches to Blackpool, 35 m.; to Lytham, about 43 m.; and to Thornton-Cleveleys, 10 m. The work was commenced in April, 1846. An act of 1846 sanctions the amalgamation of the Preston and Wyre Railway, Harbour, and Dock Company with the Corporation of the Borough of Preston, the latter of which have the option of purchasing the portion between Rickegate and Docking. By a proposed arrangement with the Direct London and Portsmouth Railway Company for the use of part of their line, the construction of about 11 m. of this line may be avoided.
Redruth and Chassewater (or Dewern).—[P. C. p. 265.]
Redruth, Cornwall.—From the London and South-Western Railway at Battersea, through Woodworth and Putney, to Richmond, length 6 m.; act passed 1846. Sold to the London and South-Western Railway Company.
Royston and Hitchin.—Length, about 12 m.; act passed 1846. This is the only part of the extension line of the Camberley and Oxford Railway, a far more extensive project. It is proposed to extend the line from Royston to Cambridge, and to lease or sell it to the Great Northern Railway Company. Sold to the London and South-Western Railway Company.
Rugby and Leamington.—Length 142 m.; act passed 1846. This line, which was projected to extend to Warwick, has been sold to the London and Birmingham Company, and the provision of a station at Rugby it constitutes.
Rugby and Stamford.—From the Rugby station of the London and Birmingham Railway to the System and Peterborough line of the Midland Railway near Stamford; length nearly 30 m. The act, which was passed in 1846, was obtained by the London and Birmingham Company, and a station at Rugby it constitutes.
Salisbury Branches.—See London and South-Western.
Sandhurst.—[P. C. p. 265.]
Sandhurst.—In 1842 the company obtained an act for an extension of the line from the town of Eton to the town of Sandhurst, amounting together to 34 m., for mineral traffic and horse-power. See Eton, Sandhurst, and South Wales.
Selby Market Vice.—See York and North Midland.
Severn and Wye—[originally Lye-didbrook.]
Sheffield, Ashton-under-Lyne, and Manchester.—[P. C. p. 265.]
Sheffield, Ashton-under-Lyne, and Manchester.—The main line, and a branch of 24 m. to Ashton, made under an act of 1844, were completed in December, 1845. Acts of 1846 sanctioned branches of 1 m. to Dukfieldfield; of 1 m. to Glossop (this branch having been made without parliamentary powers, and opened in 1845); of 124 m. to Whaley Bridge, and of 24 m. to Hayfield; the purchase of the Peak Forest and Mex-}

**Digitized by Google**
a branch of 4½ m. to Coalbrook Dale, making a total of 34 m. These lines form part of a much more extensive scheme, the objects of which are to be attained by means of complicated arrangements, which led to the formation of the South Staffordshire Junction Railway Company (with which this company is amalgamated or united for the purpose of making the line granted to the tramway between Shrewsbury and Wolverhampton as much of the line granted to the other company, as lies between Titterhall and Wolverhampton), the Birmingham, Wolverhampton, & Wolvercote Tramway Company, and the Shropshire Union Railways and Canal Company. All of the lines granted to these companies may be regarded as parts of a system of communications connected with the London and North-Western Railway.

Shrewsbury and Chester.—This is the title given by an act of 1842 to the line from Shrewsbury to Chester Junction and the North Wales Mineral Railways, which see.

Shrewsbury and Hereford.—Length, 10½ m.; act passed 1845. Fostered by a local board of trade, it was an original project of the Great Western Railway Company, in opposition to a similar line promoted by the Great Western Railway Company.

Shrewsbury, Chester, and Chester Junction.—From Shrewsbury to the North Wales Mineral Railway at Cefn Mawr, with branch to Oswestry; length 23½ m.; act passed 1845. Acts of 1844 to 1847, for tramway and railway respectively, for the formation of a tramway and railway between Shrewsbury and Chester Junction, and the North Wales Mineral Railways, under the name of the Shrewsbury and Chester Railway.

Shrewsbury and Chester.—See Shropshire Union Railway and Canal Company, and South Staffordshire Junction Railway.

Shrewsbury and Chester, and Shrewsbury and Chester Junction.—Length, main line from Shrewsbury to Wolverhampton, rather over 29½ m.; branch at Shrewsbury, nearly 1 m.; act passed 1846. Under the form of a horse tramway, a branch to Oswestry was proposed to be connected with the Shrewsbury and Chester Railway, a considerable portion of this line will be abandoned, the two companies uniting to execute certain portions of the works projected by each.

Shropshire Union Railways and Canal.—Three acts were obtained in 1846 by a company with the above title, authorizing, respectively, the formation of a railway of nearly 46 m. from the Chester and Crewe branch of the Grand Junction Railway, at Calveley, to Wolverhampton, called the Chester and Wolverhampton Railway Company, and an additional power to purchase and to convert part of it into a railway; the formation of a main line of railway of nearly 60 m. from Newtown, in the county of Hereford, to Oswestry, with branches to Ellesmere, Wem and Whitlock, and one at Crewe, amounting to 7½ m.; and the formation of a main line of railway of rather over 39 m. from Shrewsbury to Stafford, with a branch of 1½ m. to Stone, including power to purchase the Shrewsbury Canal. The aggregate length of the above lines is rather over 155 m., but the company are restricted from making that portion of the last-mentioned line which lies between Shrewsbury and Wellington, in case either the Shrewsbury and Birmingham or the Shrewsbury, Wolverhampton, and Staffordshire Railways should obtain their act, which both did, although, as explained under Shrewsbury and Birmingham, only part of the scheme of each is to be executed. Arrangements were also made for the leasing the whole of the above undertakings to, or the amalgamation of the company with, the London and North-Western Railway Company. The Shrewsbury and Chester Junction Railway Company possess an interest in the Shropshire Union.

Sirkewy.—[P. C., p. 265.]

South Eastern.—The Bristol and Exeter Railway at Exe- ter to Plymouth; length, about 54½ m., exclusive of a branch of about 2½ m. to Mill Bay, and an alteration of about 2 m. of the Plymouth and Dartmouth Railway, which the company are empowered to lease or purchase; act passed 1844; gauge 7 feet. Intended for working by atmospheric power; but 15 m., from Exeter to Exmouth, was obtained under an act of 1846, was empowered to be leased or purchased, and was taken over by the Plymouth and Devonport Company. The act of 1846 sanctions a branch of 5 m. from Aller, near Newton, to Torgusy; a deviation of the main line near Newton, to Wolmerhampton, as already authorized in the town of Plymouth and Devonport. Part of the capital for this line was subscribed by the Great Western, Bristol and Exeter, and Bristol and Gloucester Railway Companies, which are empowered to lease it; and the South Devon Company possesses an interest in the Ashburton, Newton, and South Devon and the Cornish line.

South-Eastern.—[P. C., p. 265.]

South-Western.—The Bristol and Exeter Railway at Exeter to Plymouth; length, about 54½ m., exclusive of a branch of about 2½ m. to Mill Bay, and an alteration of about 2 m. of the Plymouth and Dartmouth Railway, which the company are empowered to lease or purchase; act passed 1844; gauge 7 feet. Intended for working by atmospheric power; but 15 m., from Exeter to Exmouth, was obtained under an act of 1846, was empowered to be leased or purchased, and was taken over by the Plymouth and Devonport Company. The act of 1846 sanctions a branch of 5 m. from Aller, near Newton, to Torgusy; a deviation of the main line near Newton, to Wolmerhampton, as already authorized in the town of Plymouth and Devonport. Part of the capital for this line was subscribed by the Great Western, Bristol and Exeter, and Bristol and Gloucester Railway Companies, which are empowered to lease it; and the South Devon Company possesses an interest in the Ashburton, Newton, and South Devon and the Cornish line.

South-Eastern.—[P. C., p. 265.]

South-Western.—The Bristol and Exeter Railway at Exeter to Plymouth; length, about 54½ m., exclusive of a branch of about 2½ m. to Mill Bay, and an alteration of about 2 m. of the Plymouth and Dartmouth Railway, which the company are empowered to lease or purchase; act passed 1844; gauge 7 feet. Intended for working by atmospheric power; but 15 m., from Exeter to Exmouth, was obtained under an act of 1846, was empowered to be leased or purchased, and was taken over by the Plymouth and Devonport Company. The act of 1846 sanctions a branch of 5 m. from Aller, near Newton, to Torgusy; a deviation of the main line near Newton, to Wolmerhampton, as already authorized in the town of Plymouth and Devonport. Part of the capital for this line was subscribed by the Great Western, Bristol and Exeter, and Bristol and Gloucester Railway Companies, which are empowered to lease it; and the South Devon Company possesses an interest in the Ashburton, Newton, and South Devon and the Cornish line.

South-Eastern.—[P. C., p. 265.]

South-Western.—The Bristol and Exeter Railway at Exeter to Plymouth; length, about 54½ m., exclusive of a branch of about 2½ m. to Mill Bay, and an alteration of about 2 m. of the Plymouth and Dartmouth Railway, which the company are empowered to lease or purchase; act passed 1844; gauge 7 feet. Intended for working by atmospheric power; but 15 m., from Exeter to Exmouth, was obtained under an act of 1846, was empowered to be leased or purchased, and was taken over by the Plymouth and Devonport Company. The act of 1846 sanctions a branch of 5 m. from Aller, near Newton, to Torgusy; a deviation of the main line near Newton, to Wolmerhampton, as already authorized in the town of Plymouth and Devonport. Part of the capital for this line was subscribed by the Great Western, Bristol and Exeter, and Bristol and Gloucester Railway Companies, which are empowered to lease it; and the South Devon Company possesses an interest in the Ashburton, Newton, and South Devon and the Cornish line.

South-Eastern.—[P. C., p. 265.]

South-Western.—The Bristol and Exeter Railway at Exeter to Plymouth; length, about 54½ m., exclusive of a branch of about 2½ m. to Mill Bay, and an alteration of about 2 m. of the Plymouth and Dartmouth Railway, which the company are empowered to lease or purchase; act passed 1844; gauge 7 feet. Intended for working by atmospheric power; but 15 m., from Exeter to Exmouth, was obtained under an act of 1846, was empowered to be leased or purchased, and was taken over by the Plymouth and Devonport Company. The act of 1846 sanctions a branch of 5 m. from Aller, near Newton, to Torgusy; a deviation of the main line near Newton, to Wolmerhampton, as already authorized in the town of Plymouth and Devonport. Part of the capital for this line was subscribed by the Great Western, Bristol and Exeter, and Bristol and Gloucester Railway Companies, which are empowered to lease it; and the South Devon Company possesses an interest in the Ashburton, Newton, and South Devon and the Cornish line.

South-Eastern.—[P. C., p. 265.]

South-Western.—The Bristol and Exeter Railway at Exeter to Plymouth; length, about 54½ m., exclusive of a branch of about 2½ m. to Mill Bay, and an alteration of about 2 m. of the Plymouth and Dartmouth Railway, which the company are empowered to lease or purchase; act passed 1844; gauge 7 feet. Intended for working by atmospheric power; but 15 m., from Exeter to Exmouth, was obtained under an act of 1846, was empowered to be leased or purchased, and was taken over by the Plymouth and Devonport Company. The act of 1846 sanctions a branch of 5 m. from Aller, near Newton, to Torgusy; a deviation of the main line near Newton, to Wolmerhampton, as already authorized in the town of Plymouth and Devonport. Part of the capital for this line was subscribed by the Great Western, Bristol and Exeter, and Bristol and Gloucester Railway Companies, which are empowered to lease it; and the South Devon Company possesses an interest in the Ashburton, Newton, and South Devon and the Cornish line.
of less than 1 m. The gauge of the line is a ft. 8½ in. See Abber- 
dore.

Tow Vale [P. C. p. 265].—An amendment act passed in 1845; and in 1846 the company obtained powers for extending the line to Crendon: to be named the Oxford, Buckingham, and Reading Railway, at a distance of nearly 31 m. An arrangement for leasing the line to the Bristol and Exeter Railway Company has been completed.

Tetsy, Sandersfoot, and South Wales.—The act, passed in 1846, is for "making a Railway to connect the Sandersfoot Rail- way with the Harbour of Sandersfoot, and with the Town of Tenby." Main line, from the South Wales Railway at Reynalton to Tenby, nearly 63 m.; branch to Pwllheli, 2 m.; and connection with the South Wales Railway, 2 m. The act gives power to purchase the Sandersfoot Railway and Harbour.

Waves Haven Dock and Railway [P. C. p. 265].—This project has not been carried into effect; but in 1846 the company obtained an act for continuing their powers for a further period of five years, the carrying it having been obtained in 1845.

Trent Valley.—From the Grand Junction Railway near Staff- ford to the London and Birmingham Railway at Rugby; length, 49 m.; act passed 1845. Sold to the London and North-Western Railway Company, and merged in the London and North-Western Railway.

The Vale of Midland and Grand Junction.—Main line, from Wallsall to the Midland Railway at Walshe Ford, in Ta- terhill, 161 m.; branch to join the Trent Valley Railway at Lichfield, 6 m.; act passed 1845. This line is part of a main London and Manchester line which will be supplemented by other lines, is amalgamated with the South Staffordshire Junction, under the name of the South Staffordshire Railway.

The Vale of North-Western.—From the Vale of Lea to the Vale of South-Eastern.

Vale of Neath.—Main line, from the South Wales Railway, near Neath, to Merthyr Tydfil, nearly 223 m.; four branches, one of which, the branch to Neath, is one of the most important. Act passed 1846. To be laid on the 7½ feet gauge, as a branch of the South Wales Railway, to the proprietors of which it may be leased or sold.

Wakefield, Pontefract, and Goole.—The original act, passed in 1845, is for a line from the Manchester and Leeds Railway at Wakefield to Pontefract and Goole, with some short branches, amounting altogether to 283 m. Others, obtained in 1846, sanction the construction of a jetty and other works at the port of Goole, and power to branch lines amounting to about 15 m., consisting of the Methley branch, of nearly 44 m.; the Askern branch, 104 m.; and the Oakeshaw branch, of rather over 4 m. The line is to be amalgamated with the Manchester and Leeds Railway.

Warwich and Leamington Union.—From the London and Bir- mingham Railway at Coventry to a point about midway between Warwich and Leamington; length rather under 9 m.; act passed 1845; opened December, 1844. Sold to, and made by, the London and Birmingham Railway Company.

Warley.—From the Bishop's Auckland and Wearhead Railway to Frosterley, with a branch to Bishopsgarth; total length 11½ m.; act passed 1846. The line is to be built by the Bishop's Auckland and Wearhead Railway, with its short connected lines for mineral traffic, the Wear and Derwent, and Wearhead Extension Railways; and the Bishop Auckland and Wearhead Railway Act, which is to establish a more direct connection between the Bishop's Auckland and Wearhead and the Stockton and Darlington railways than that afforded by the Black Boy branch. The three last-mentioned undertakings have been executed without parliamentary powers.

Weardale Extension.—See Wear Valley.

Wexford and Northampton.—See London and Birmingham.

West Cornwall.—Main line, from the parish of Krynwo to Penzance, nearly 26 m.; branch from near Redruth to the Corn- wall Railway near Penzance, to complete the communication between Falmouth and Penzance, 5½ m.; total, about 313 m. To be laid on the broad gauge. The act, passed in 1846, gives powers to build this line.

West London (formerly Birmingham, Bristol, and Thames Junction).—The main line was laid down with a single track, but three rails, forming a double gauge, and worked by locomotive engines. Laid for 999 years to the London and Bir- mingham Railway line; and the company are authorised to obtain an act jointly in 1846 for altering about 1 m. of the line, and extending it nearly 3 m. to the river Thames at Chiswell.

Whaleysdale.—From Skipworth to the Leeds and Thirsk Railway at Archington, 21 m.; and two short branches, one at Skipworth, and one to form a second junction with the Leeds and Thirsk line, about 1 m. total 23 m.; act passed 1846. It was proposed to lease this line to the London and North-Western Railway; but the Yorkshire North-Eastern Railway, and intended to extend to York, to the Leeds and Thirsk Railway Company; but (Novem- ber, 1846) the tenements have been secured for an extension to Whitby and Pickering [P. C. p. 265].—Purchased by the York and North Midland Railway Company, who obtained an act in 1845 for a tunnel through the mountains of Yorkshire in order to extend to York in 1846 for an extension of about 103 m. to near Castleton.

Whitehaven and Furness Junction.—Crosses the Duddon sands; length, with two branches, 8 m.; act passed 1844. The act passed 1845. An act of 1846 allows a deviation of nearly 3 m. at Kirkcudart; an extension of 5 m. at Whitehaven, to join the Whitehaven and Port Carlisle Railway; and the line is to be under- taken to the Whitehaven Junction Railway Company.

Whitehaven Junction.—From the Maryport and Carlisle Rail- way at Maryport, along the coast, to Whitehaven; length 22 m.; act passed 1844; part opened 1846. See Whitehaven and Furness Junction.

Wigan Branch [P. C. p. 265].—See North Union.

Wilt, Sommerset, and Weymouth.—Under the original act of 1845 this railway is to extend from Corsham, on the Great Western Railway, by two main branches, amounting to about 96 m., with smaller branches to Devizes, 7 m.; Bradford, 1½ m.; Radstock, 9 m.; Sherborne, 4 m.; and Bridport, 1½ m.; total 129 m.; but an act of 1845 authorises a second branch from the Devizes and Bradford, and the whole to nearly 363 m., of which length about two-thirds is to replace parts of the original scheme which have been abandoned. The additions are:—from Corsham to Devizes, 6 m.; from Sherborne to Melcombe Regis, 2 m.; and from the Weymouth extension, nearly 1 m.; the Salisbury extension, 2½ m.; the Devizes branch (substituted for that of 1845), 6½ m.; and the branch to Yeovil, 1½ m.; the Laycock devi- sion and junction extension, 1 m.; the Weymouth extension, nearly 3 m.; the Weymouth extension, nearly 1 m.; the Salisbury extension, 4½ m.; the Devizes branch (substituted for that of 1845), 6½ m.; and the branch to Yeovil, 1½ m.; the Laycock devi- sion and junction extension, 1 m.; the Weymouth extension, 3 m.; the Fovant deviation, 6½ m.; the Red- stock branch deviation, 1 m.; and the Herringstone deviation, 4 m. The undertaking was projected in connection with the Great Western Railway Company, whose gauge is to be adopted.

Windsor, St. Ives, and Cambridge Junction.—Main line, from Wobbech to St. Ives, 271 m.; branches to head of railway at Cambridge, 18 m.; and bridge and Huntingdon line of the Eastern Counties Railway at Penny-Drayton, 1½ m.; total 29 m.; act passed 1846. Sold to the Eastern Counties Railway Company.

Yarmouth and Norwich.—Act passed 1842; opened May, 1844. Length 20½ m. Amalgamated with the Norwich and Brad- waxdon, under the name of the Norfolk Railway, which see. See also Lowestoff. The amalgamation act of 1845 sanctioned an extension of about 4½ m. at Norwich. The connection with the Brandon line near that city by a movable bridge over the Wes- sum was completed in December, 1845.

Yewell Branch.—See Britoil and Exeter.

York and Beverley.—See York and North Midland.

York and Beverley.—See York and North Midland.

York and Newcastle Union.—This is the name given by an act of 1846 to the Newcastle and Darlington Junction Railway, with the Great North of England, and other lines now associated with it. According to a statement annexed to the act, the company, in October, 1846, agreed on the length of the lines beyond to this company, or which they have power to construct, is about 225 m.

York and North Midland [P. C. p. 265].—By an act of 1844, this company was empowered to make a line of about 42 m. from York to Scarborough, with a branch of 6½ m. to Pickering. The Scarborough branch, an alteration of which for 8 m. near York was sanctioned by an act of 1845, was opened in July of that year. Other acts of 1845 authorises a branch of 191 m. from the York and Scarborough line to Bridlington, which was opened as far as Filey, about 6 m., in October, 1846; and a branch of 194 m. from their main line to Harrogate. Acts of 1846 authorises the York and Beverley Railway of rather over at m. to the East Dock branch of 4 m., making together 35 m.; the Selby and Market Weighton branch of 16 m. with the Hornsea branch of 194 m.; together making a new line of 260 m. of direct communication between York and Leeds; the widening and en- largement of about 138 m. of the original York and North Mid- land line, and the extension of the main line, 14 m., with an additional new line of about 138 m. of the original York and North Mid- land line, and the extension of the main line, 14 m., with an additional new line of about 138 m.
RAILWAYS OF SCOTLAND.*

Aberdeen.—From Aberdeen to the Aberroth and Forfar line at Fyvie, 492 m.; branch to form a second junction at Guthrie, 50 m.; and to Montrose, 56 m.; branch to Brechin, 58 m.; and to Arbroath, 58 m.; act passed 1845. To lease the Arbroath and Forfar Railway. See also Duntoit.

Arbroath and Forfar. [P. C., p. 265.]—An act of 1846 sanctions the leasing of the line to the Aberdeen Railway, in consequence of which the gauge will be widened to 4 ft. 8½ in., and a second track will be laid.

Ardsrossan (formerly Johnstone and Ardsrossan). [P. C., p. 265.]*—Gauge originally 4 ft. 6 in., but altered to 4 ft. 8½ in., for railway, together with the harbour of Ardsrossan, has been sold to the Glasgow, Kilmarnock, and Ardrossan Railway Company.

Ayrshire and Bridge of Weir.—From the Glasgow, Paisley, Kilmarnock, and Dunbartonshire Railway Company. [Balloch, p. 265.]*—Gauge originally 4 ft. 6 in., but altered to 4 ft. 8½ in., under an act of 1845. See Monkland and Clydesdale Junction. See also Glasgow, Balloch, and Helensburgh Direct; Glasgow, Kilmarnock, and Ardrossan; Glasgow Southern Terminal, and Scottish Central. The company also proposes to amalgamate with the Glasgow, Paisley, and Greenock.

Caledonian and Dumfriesshire Junction.—According to the title of the act, which was passed in 1846, this is a railway 'from Glasgow, Kilmarnock, and Lochmaben, to Briggend, and to Kilmarnock, and the purchase of the Glasgow, Garnkirk, and Coatbridge line, are sanctioned; and the Caledonian Company are empowered to devote their line to it; to devote about 3 m. of the Clydesdale Junction line; to form short branch and terminal railways at Glasgow, amounting to about 2 m.; and to make branches amounting to 14 m. from their Cessnock railway to Garnkirk, and to Coatbridge Railway. See also Glasgow, Barrowhall, and Neilston Direct; Glasgow, Kilmarnock, and Ardrossan; Glasgow Southern Terminal, and Scottish Central. The company also proposes to amalgamate with the Glasgow, Paisley, and Greenock.

Caledonian and Dunbartonshire Junction.—From the Paisley and Glasgow Railway Company, whose line it joins at Dunblane. See also Glasgow, Paisley, Kilmarnock, and Ayr.

Edinburgh and Arbroath. [P. C., p. 266.]*—Gauge to be altered to 4 ft. 8½ in. An act of 1846 authorizes a branch to Broughty Ferry Castle, and another to the Arbroath and Forfar line at Almerieclees. Length, under 14 m.

Dundee and Arbroath. [P. C., p. 266.]*—Leased to the Dundee and Arbroath Company, with the Arbroath and Forfar line at Almerieclees. Length, under 14 m.

Dundee and Broughty Ferry. [P. C., p. 266.]*—Original gauge 4 ft. 6 in.; act passed 1846.

Dundee and Perth.—Length, 204 m.; act passed 1845. A second act, of 1846, sanctions some deviations in the line, a short extension at Perth; and the leasing or purchase of the Dundee and Broughty Ferry Railway.

Dumblane, Doune, and Callander.—Length 104 m.; act passed 1846. Power given to lease to the Scottish Central Railway Company, whose line it joins at Dunblane. See also Glasgow, Paisley, Kilmarnock, and Ayr.

Dundee and Broughty Ferry.—From the Edinburgh and Broughty Ferry Railway at Kirkaldy, near the railway station, to Dundee, 35 m.; act passed 1846. Length, 204 m.; controlling, 12 m.; through line, 192 m.; cost £85,000; earnings £12,000; passengers about 140,000. See also Dundee and Arbroath.

Dundee and Stobswell.—Original gauge 4 ft. 6 in.; act passed 1846. A second act, of 1846, sanctions some deviations in the line, a short extension at Stobswell, and the leasing or purchase of the Dundee and Perth Railway.

Dundrum Bridge.—See the Arbroath and Forfar Railway, and to the Edinburgh and Broughty Ferry Railway at Broughty.

Edinburgh and Broughty Ferry.—Main line, 192 m.; near the station of the Edinburgh and Broughty Ferry Railway, to Broughty Castle, 16 m.; and to Milton of Leith, 1 m.; act passed 1846. A second act, of 1846, sanctions some deviations in the line, a short extension at Broughty Ferry, and the leasing or purchase of the Dundee and Perth Railway.

Edinburgh and Leith.—Main Line, 192 m.; near the railway station of the Edinburgh and Broughty Ferry Railway, to Broughty Castle, 16 m.; and to Milton of Leith, 1 m.; act passed 1846. A second act, of 1846, sanctions some deviations in the line, a short extension at Broughty Ferry, and the leasing or purchase of the Dundee and Perth Railway.

Edinburgh and Leith.—[P. C., p. 266.]*—Opened September 15, 1845. Act of 1845 authorised an extension of 14 m. from Edinburgh to Leith, to join the North British and Edinburgh, Leith, and Granton Railways at the North Bridge, which extension was opened on December 27th, 1845. Act of 1846 authorizes the extension of nearly 6 m. from Leith to Granton Railway, on the South Queensferry. Arrangements had been made by the Directors for amalgamating with, or lessening, the Montrose, Broughty Ferry, Balloch, and Slanemans lines; the Airdrie and Bathgate Junction; the Edinburgh and Bathgate; the Glasgow, Airdrie and Dalmuir; the Linlithgowshire Midland Junction; and the Wishaw and Coltness Railways; and also the Forth and Clyde Canal; but in September, 1846, the canal amalgamation was broken off, and a subsequent change of directors may probably be followed by the abandonment of other contemplated arrangements. It is reported (November, 1846), that the Granton Coltness line has been purchased by this company and taken up by the Caledonian Railway Company. See also Caledonian and South North British.

Edinburgh and Hawick.—This line, branching out of the North British Railway near Newcastleton, and forming a junction at Hawick with the South Bank of the Tweed and Dalkeith line, has been amalgamated with the North British. Length, 453 m.; act passed 1845. The bill for a proposed extension to Carlisle was lost in 1845. For branches see North British.

Edinburgh, Leith, and Granton (originally Edinburgh, Leith, and Northburn). [P. C., p. 266.]*—The name was changed in 1844, by an act which authorised a new branch of 14 m. from Edinburgh station, to Leith and Granton, and one of 1 m. to Granton. The total length of the present lines is nearly 44 m. Part of the main line was opened in 1845, and the branches and tunnel to Kinghorn Street, 1846. The company proposes to amalgamate with the Edinburgh and Northern Railway Company.

Edinburgh and Northern.—By the original act of 1845 this is a main line of 304 m. from Burntisland, on the Firth of Forth, to Perth, with a branch of 24 m. to Cupar and Coupar, and one of 1 m. to Kinnoull. The line was opened in 1845, and the branch is within 15 m. of the Forth Railway. See also Perth and Dundee Railway. The line is expected to be connected with the extension of the North British Railway at Dunfermline, by a line of 10 m. to Cupar, and of 600 yards from Kinross to Pet- tycour. Another act authorizes the purchase of a line of 40 m. Another act allows the purchase of the ferry across the Tay between Ferry-Port-on-Craig and Broughty. See also Edinburgh, Leith, and Granton.

Garpkirk and Glasgow. [P. C., p. 266.]*—The original gauge of this line was 4 ft. 6 in., and not, as stated there, 4 ft. 8½ in.; but it is proposed by an act of 1844 that an act to be increased to 4 ft. 8½ in. is about to be passed, 1846; authorizing extensions to the amount of 24 m., the name of the company was changed to the Glasgow, Garnkirk, and Coatbridge Railway Company. See also General Terminus and Glasgow Harow.

General Terminus and Glasgow Harbour.—From the Pollok and Glasgow Railway to the river Clyde and the harbour of Glasgow, 1 m.; act passed 1844. Power given to lease to the joint undertaking of the Glasgow, Paisley, Greenock, and Glasgow, Paisley, Kilmarnock, and Ayr Railways, and to the Glasgow, Barhead, and Neilston Direct line; total length, under 24 m.; act passed 1846. See also Glasgow, Airdrie, and Monklands Junction.

Glasgow, Barrowhall, and Neilston Direct.—From Glasgow to Croftonhall, Neilston, and branches of 16 m. to Greenock and Dunbarton, and the Greenock Railway. Act passed 1845. Under an act of 1846 branches to Thornhillbank and Nithshill, together under 14 m., are authorised to be connected with the Glasgow, Paisley, and Neilston Direct; this undertaking is to be leased to the Caledonian. See also Glasgow, Kilmarnock, and Airdrossan, and Glasgow, Strathaven, and Lemasdale.

Glasgow and Belford Union.—From the Glasgow, Paisley, Kilmarnock, and Ayr line (to the owners of which it is to be made over by the company), to the haulage of the Thomson and Railway, between under 14 m., with a branch of 3 m. to Ayr; act passed 1846. This is only a part of a much more extensive project.

Glasgow, Dumfries, and Carlisle.—From the Glasgow, Paisley, Kilmarnock, and Ayr Railway, near Cumnock, to the Caledonian Railway, and to the crossing of the river Sark, nearly 65 m.; with branches of 1 m. to Annan, under 14 m.; to the Glasgow, and under 14 m. to Cradock, 165 m.; total, 907 m. Act passed 1846. To be nearly 114 m.; with Calder branch, nearly 24 m.; Binny quarries branch, 11 m.; Whithorn branch (from Barrack), nearly 24 m.; Whithorn branch (from Bathgate), nearly 3 m.; total, about 254 m. Act passed 1846. Leased to the Edinburgh and Glasgow Railway Company.

* In the case of several of the earlier Scotch railways the gauge is given erroneously as 4 ft. 6 in., which is not the case; it is, however, as given in the above table in which the matter is noticed, most of them were laid with a gauge of 4 ft. 6 in., and others will be too long, altered to the ordinary 4 ft. 8½ in. gauge of 4 ft. 8½ in.
amalgamated with the Glasgow, Paisley, Kilmanock, and Ayr, and the portion from Dunbarton to Grefina to be worked by the Caledonian Railway Company.

Glasgow, Garnkirk, and Coatbridge. — This railway is the line originally called the Garnkirk and Coatbridge (which see), as extended under an act of 1844 by new lines, one of which joins the Wishaw and Coltness, to the extent of 2½ m. Of these the Garnkirk and Coatbridge branch was opened in 1845, in which year an act was obtained to widen the gauge to 4 ft. 8½ in. Under three new acts of 1846 the line is termed 3½ m in connection with the Glasgow and the connection mentioned under Caledonian is sanctioned.

Glasgow Junction. — From the Edinburgh and Glasgow Railway at Portobello to the Cut of Juncton Canal, or near Broxburn, and to the north quay of the harbour of Glasgow. To be made by the Edinburgh and Glasgow Railway Company. Length, under act of 1845, 2½ m; but by an act of 1846 a length of 425 yds is to be abandoned, and a new line of 372 yds substituted for it.

Kilmarnock and Ayr. — From the Glasgow, Barrhead, and Neilston Direct Railway at Crofthead to Kilmarnock, 14 m; Ayrdoon branch, nearly 10 m; Irvine branch, Glasgow, Ayr, and Kilmaurs, and Neilston Direct Railway. See also Glasgow, Barrhead, and Neilston. To be amalgamated with the Caledonian.

Renfrew. — From the Glasgow, Barrhead, and Neilston Direct Railway near Pollokshaws to the Govan Railway. See also Glasgow, Barrhead, and Neilston. To be amalgamated with the Caledonian.

Glasgow Southern Terminus. — From the Glasgow, Barrhead, and Neilston Direct to the Caledonian Railway; length rather over 1 m; act passed 1846. Part of a more extensive project; and is to be made over to the Glasgow, Barrhead, and Neilston Direct Company.

Glasgow, Strathclyde, and Lomondshaws Direct. — From the Glasgow, Barrhead, and Neilston Direct Railway near Pollockshaws, to Strathclyde; length 1½ m; act passed 1846. Great North of Scotland. — From Aberdeen to Inverness, with branches to Balloch, Garmouth, and Beragh. Main line, 107½ m; branches, 35½ m; total length, 132½ m; act passed 1846. See Great North of Scotland; Eastern Extension.

Great North of Scotland. — From Aberdeen to Inverness, with branches to Balloch, Garmouth, and Beragh. Main line, 107½ m; branches, 35½ m; total length, 132½ m; act passed 1846. To be leased to the-locomotive. See Great North of Scotland.

Hawick Branch. — See Edinburgh and Hawick.

Johnstone and Ardrossan. — See Ardrossan.

Kilmarnock Branch. — See Glasgow, Paisley, Kilmanock, and Ayr.

Kilmarnock and Troon. [P. C. p. 266.]-The act of 1837, mentioned in P. C. note (b), was never carried into effect; but an act of 1846 sanctions the leasing of the line to the Glasgow, Paisley, Kilmanock, and Ayr Railway Company, the alteration of certain parts, the conversion of the whole into a locomotive line, and two new branches, amounting to 2½ m.

Leith Branch. — See Edinburgh and Dalkeith.

Monkland and Kirklistoloch. [P. C. p. 266.]-An act of 1845 authorised new branches amounting to about 1½ m, and one of 1846 sanctions a branch of 2 m. 1100 yds to Chapel Hall. and one of 23½ yds to the Glasgow, Garnkirk, and Coatbridge Railway. The original gauge of the line was 4 ft. 8½ in., but an act of 1845 provides for an alteration to 4 ft. 8 in. See Monkland Mineral.

Monkland Mineral. — This is the collective title of the Monkland and Kirklistoloch, Slammanan, and Ballochory Railways, which have amalgamated with one another, though without the sanction of Parliament, and have leased to the Glasgow, Ayr, and Monkland Junction line. It was agreed to amalgamate the whole with the Edinburgh and Glasgow; but as the machinery and expense of extending the arrangements out of the line mentioned (November, 1846) is very uncertain.

Morayshire. — From Stotfield and Leenshore Harbour to Elgin, Arders, and Croggaich; length 11 m; act passed 1846.

Nerlyte and Corpse Angus. [P. C. p. 266.]-Purchased by the Scottish Midland Junction Railway Company, to form part of their line.

Nerlyte and Glamis. [P. C. p. 266.]-Length, 7½ m. Purchased by the Scottish Midland Junction Railway Company to form part of their line.

North British. — Main line, from Edinburgh to Berwick 573 m; branch to Haddington, 42 m; act passed 1844; opened 1845. The act of 1845 sanctioned a branch of 1 m, opened in 1846, in which year an act was obtained to widen the gauge to 4 ft. 8½ in. Under three new acts of 1846 the line is termed 3½ m in connection with the Edinburgh and Dalkeith line; for making new branches to the extent of about 1¾ m, composing the Tranent branch, of ½ m, the Cockenzie branch, of nearly 1½ m, the North Berwick branch, of about 4½ m, and the Dunsie branch, of rather more than 9 m; and also for making new branches to the extent of about 25 m, in connection with the Hawick line, consisting of the Selkirk branch, nearly 5 m, the Jedburgh branch, nearly 7½ m; Paisley and Renfrew. [P. C. p. 266.]-Gauge, 4 ft. 6 in. Both passengers and goods. See Clyde Railway. Amalgamated, under an act of 1846, with the Caledonian Railway.

Scottish Central. — The original act, passed in 1845, was for a main line of nearly 465 m, from the Edinburgh and Glasgow Railway, by Stirling to Perth, with a branch to Falkirk, to the Kilmarnock and Ayr, and others, passed in 1846, sanction branches of 44 m, by Alloa to Tullibody; of nearly 9½ m to Crieff; and of 3½ m to Bridgeport, with branches of 3 m each, for making new branches to the extent of about 8 m, for making new branches to the extent of about 16½ m, for making new branches to the extent of about 1 m, for making new branches to the extent of about 1 m, for making new branches to the extent of about 17 m, for making new branches to the extent of about 25 m, in connection with the Hawick line, consisting of the Selkirk branch, nearly 5 m, the Jedburgh branch, nearly 7½ m; Paisley and Renfrew.

Dundas, Dalkeith, and Neilston. — See Clyde Railway.

Clyde Railway. Amalgamated, under an act of 1846, with the Caledonian Railway.

Scottish Midland Junction. — The original act, passed in 1845, was for a main line of 303 m, from Perth to Forfar, with short branches, increasing the length to 235 m, to connect it with the Scottish Central and Arbroath and Forfar Railways. An act of 1846 sanctions additional branches to the extent of nearly 16½ m, consisting of the Dunkeld branch, 8½ m, the Blairgowrie branch, 5 m, and the Kirriemuir branch, over 23 m. The company have purchased the Nerlyte and Corpse Angus and Ballochory, the Glasgow and Glamis Railways, which will be altered so as to form part of their main line. It had agreed to amalgamate with the Edinburgh and Glasgow and Scottish Central Railway Companies, before their contemplated union was broken off.

Shotts and Wishaw. — See Wishaw, Morningside, and Coltness.

Slammanan. [P. C. p. 266.]-The original projected branch to Ruthgate not having been executed, the company obtained an act in 1845 for a main line of nearly 41½ m, with two branches, to Pathhead, and to the northern terminus of the Slammanan Railway to the Frith of Forth, and thence to the town or harbour of Borrowstounness, 14½ m; and two branches to the Edinburgh and Glasgow Railway, about 12½ m., total length, 62 m. Act passed 1846. To be made by the Slammanan Railway Company, which see.

Slammanan Junction. — A line of about 1 m, to connect the Slammanan and Edinburgh and Glasgow Railways. Act passed 1844; continuing power to lease or sell the line to the Edinburgh and Glasgow or Slammanan Railway Companies. See Slammanan.

Stirling and Doonformine. — Main line, 25 m; branches from near Alloa to Tullibody and the harbour of Alloa, 32 m; total 244 m; act passed 1846. Proposed to be leased to the Edinburgh and Glasgow Railway Company. See Stirlingshire Midland Junction.

Stirlingshire Midland Junction. — Main line, from the Edinburgh and Glasgow Railway to the Scottish Central Railway, 54 m; branch to Carron iron-works, 14½ m; branch to Falkirk iron-works, 3 m; act passed 1846. Sold to the Edinburgh and Glasgow Railway Company.

Strathtay and Breadalbane. — From the line of the projected...
Perth and Inverness Railway, (a scheme abandoned for the present during the session of 1846) to Aberfeldy; length, nearly 92 m.; act passed 1846.

**Railways of Ireland.**

Belfast and Ballymoney—Main line nearly 35 m.; Carrickfergus branch 14 m.; Sandalstown branch 2 m.; total length, 38 m.; act passed 1845.

Belfast and Downhill. [P. C. p. 267.]

Belfast and County Down. From Belfast to Downpatrick 244 m.; with branches to Holywood, Newtownards, Bangor, and Donaghadee, amounting to 304 m.; total length, 462 m.; act passed 1845.

Clonmel and Thurles. From the Waterford and Limerick Railway at Clonmel, to the Great Southern and Western Railway atTZ—Caledonian Railway, with a branch from the latter to a station at Granville, in the parish of Slieve, making a total of 5 m. An agreement had been made for the sale of the whole undertaking to the Edinburgh and Glasgow Railway Company; but it is now (November, 1846) expected that a union with the Caledonian Railway Company will be substituted for the intended arrangement.

**Waterford and Limerick Railway.** (Act of November, 1846.)—The Waterford and Limerick Railway was chartered by the act of 1846, 7 m. 2 s. 3 d.; with branches to New Ross, 3 m.; total length, 25 m.; act passed 1846. Sold to the Great Southern and Western Railway Company.

Cork, Blackrock, and Passage. From Cork, through Blackrock, to Passage West; length, 64 m.; act passed 1846.

Cork and Passage. [P. C. p. 266.]

Cork, Passage, and Waterford. —Main line, 78 m.; branch to Fermoy, 18 m.; branch to Tramore, 22 m.; total length, 274 m.; act passed 1846.

Dolby. —See Dublin and Kingsmont.

Dublin and Coleraine Junction. Main line from Armagh to Portrush, 70 m.; branch to Sandilands, 13 m.; branch to Ballymoney, 43 m.; total length, 774 m.; act passed 1846.

Dublin and Kingsmont. Main line, from Drogheda to Portadown, 56 m.; branch to Navan, 171 m.; act passed 1845. An agreement was made in 1846, for selling the Navan branch to the Dublin and Drogheda Railway Company.

Dublin and Drogheda. [P. C. p. 266.]

Opened May, 1846; gauge 5 ft. 6 in. An act of 1846 authorises the Howth Branch, 83 m. long, the greater part of which was opened in July, 1846. The company has purchased the Navan branch of the Dublin and Belfast Junction, which see.

Dublin and Rathfurdburn. —Dublin to Dundrum, roughly over 3 m.; branch to Rathfurdburn, over 2 m.; total length, nearly 51 m.; act passed 1846.

Dublin and Wood Green. [P. C. p. 266.]

An extension of 12 m. to Dalkey, worked by atmospheric power, was made without an act of parliament, and opened in March, 1844. It follows the line of a tramroad constructed by the trustees of Kingstown Docks. An act of 1846 authorises a further extension of 7 m. to the bridge of Bray. See Waterford, Wexford, Wicklow, and Dublin.

Dundalk and Enniskillen. From Dundalk to the Newry and Enniskillen line at Clones, 403 m.; the remaining distance, about 30 m., from Clones to Enniskillen, to be made by the Newry Company, with provisions for its joint use by both lines; act passed 1845.

Dundalk Western. [P. C. p. 265.]

An abandonment.

Galway and Kilkenny. —Main line, 147 m.; from Kilkenny to Clonmel, 47 m.; to the east of Clonmel, 23 m.; total length, nearly 217 m. The company has obtained an act of 1846, but will probably not proceed with it in the near future.

Great Leinster and Munster. [P. C. p. 266.]

Owing to financial difficulties, the act of 1837, amended by another, and passed in 1846, was never carried into effect. The Great Southern and Western line has superseded the Great Leinster and Munster between Dublin and Cashel, 145 m., and between Cashel and Cahir, 52 m. In May, 1846, a committee was appointed to report on the remaining from Cashel to Kilkenny, about 35 m., with a branch of 4 m. to Milford; and another act of the same session authorising a branch of 31 m. from Kilkenny to Clonmel, 22 m.; from Clonmel to Carrick, 33 m.; from Carrick to Waterford, 25 m. The Waterford, Carrig, and Dublin Junction line is to be amalgamated with this undertaking under the new name of the Irish South-Eastern Railway Company.

Great Southern and Western. —The main line from Dublin to Cashel, 98 m.; branch from Monasterboice to Carlow, 34 m. For these the act of 1846, 63 s. 6 d., was obtained. A second act in 1844, allowing an extension of 77 m. to Cork, with a branch of 24 m. to Limerick. The Limerick branch, however, being identical with part of the Waterford and Limerick Railway is not to be made if that line is carried into effect. Another act passed in 1846, 45 s. 6 d., authorises a branch of nearly 11 m. to the river Lee at Cork. Of the original line, the portion between Dublin and Carlow, about 264 m., was opened in August, 1846. See also Clonmel and Cahir; Kingsmont; Enniskillen and Morgan's Point; Wexford, Carrig, and Dublin; Waterford, and Enniskillen.

Kilkenny and Great Southern and Western. —From Kilkenny to the Great Southern and Western Railway near Dodderagh; length, 90 m.; act passed 1846. Part of a much more extensive scheme carried by the Kilkenny and New Ross Railway Company, power given to lease or sell the line to the Waterford and Kilkenny Railway Company.

Kilkenny Junction. —From Kilkenny to Kilkenny, length 90 m.; act passed 1846.

Limerick, Ennis, and Killaloe Junction. Main line, from Limerick to Ennis, 160 m.; branch from Limerick to Killaloe, 10 m.; branch from Limerick to Clonmel, 10 m.; branch to Clonmel and Great Southern, 10 m.; branch to the Western line, 10 m.; act passed 1846. Completed (November, 1846) from Kilkenny to Strabane. Limerick, and Fermoy. —Main line, from the Great Southern and Western Railway (with which it gains power to amalgamate) at Fermoy; length, 90 m.; act passed 1846.

Mallow and Fermoy. —The original act, passed 1846, authorises a line of 77 m. from Mallow to Killarney and Longford, chiefly running upon the banks of the Royal Canal, which has already been undertaken by the company. Acts of 1846, 60 s. 6 d., for a branch, about 30 m., to the river Liffy, at Dublin; and a deviation of 26 m. to the southward of Mallow, and a branch of 23 m. to the river Liffy, at Dublin; and a deviation of 14 m. to the southward of Mallow.

Mountrath Junction. From the Great Southern and Western Railway at Carrow or Carraghane to Mountrath; length, nearly 29 m.; act passed 1846, for the purpose of leasing or selling the line to the Great Southern and Western Railway Company.

Mullingar and Athlone. —See Midland Great Western.

Navan Branch. —See Dublin and Belfast Junction.

Newry, Warrenpoint, and Richmoun. Main line, from Newry to Warrenpoint, 44 m.; act passed 1846.

Newry and Warrenpoint. —Main line, 44 m.; branch to Warrenpoint, 3 m.; act passed 1846.

Steeple Abbey Collieries Branch. —See Clonmel and Thorles.

Sligo and Shannon. —From Leagh Allan to Leagh Gill, in the county of Leitrim; length, 13 m.; act passed 1846.

South-Eastern. —See Irish South-Eastern.

Tambourine Hill. —Main line, 44 m.; the act, passed in 1846, gives power to amalgamate, with or lease the line to, the Great Southern and Western Railway Company.

Waterford, Carrig, and Dublin Junction. —From Waterford to Carrig; length, 80 m.; act passed 1846. Power given to lease or sell the line to the Great Southern and Western Railway Company.

Wexford, Carrig, and Dublin Junction. —From Wexford to Carrig; length, 29 m.; act passed 1846. Amalgamated with the Great Leinster and Munster under the title of the Irish South-Eastern Railway Company.

**TRANSPORT.** [MILLON. P. C.]

**TRANSPORTATION.** In Music, is a change of the original key to one higher or lower. This is generally performed, as a matter of convenience, by the accompanist, rather than the reasonable convenience, but more often to gratify the whim of the singer.

To the singer TRANSPORTATION is understood by any difficulty whatever, by which the voice is not to be strained. The accompanist is to follow the compass of the voice. To the accompanist it is far otherwise. The latter, unless playing from memory, must assign to all the notes, as regards their pitch,
TRavers, John. The author of compositions so popular, elegant, and charming as 'Haste, my Nanette,'—I, my dear, was born to-day. — When Bibo thought fit,—So Soft Cupid,—is fairly entitled to a few lines in our biographical department, though his life was void of any remarkable incident. He was educated first in St. George's Chapel, Windsor, afterwards under the celebrated Dr. Greene [GREENE, P. C.]. About the year 1725 he followed Kelway as organist of St. Paul's, Covent Garden, and subsequently filled the same situation also at Fulham. In 1737 he was appointed organist to the Chapels Royal. He died in 1758, and was succeeded in the latter office by Dr. Boyce.

Travers composed much cathedral music, but except an anthem, 'Ascribe unto the Lord,' and a 'Te Deum,' his productions for the church have fallen into disuse. We will only add, that Dr. Bunney's notion of him is neither discriminating nor just.

TRavereS, P. C.)

TREnTO, Antonio da, supposed to be the same person as Antonio Fantuzzi. He was born at Trent about the commencement of the sixteenth century; and, according to Vasari, the pupil of Peter and Valetto; and, according to Parrigiano, employed Antonio to engrave his works in wood, and he was one of the first and most eminent of the Italian wood-engravers. He appears to have initiated the cuts of Hugo da Carpi. Antonio Fantuzzi, but appears to have cut a good deal of wood, and was, for about 1530, employed by his master, taking with him many of his drawings, plates, and woodcuts, and went, it is supposed, to France, where he appeared again under the name of Antonio di Trento. He attached himself in France to Pramintico, who employed him to engrave or etch some of his works in copper; he executed also etchings after some other masters while in France. Bartch describes 37 etchings by him, but he is more celebrated for his woodcuts, which he engraved in chiaroscuro. The time of his death is not known, but it happened probably about 1560: the date on his prints reach to 1546.

Some of the woodcuts of Antonio are printed with three, others with two blocks: they are chiefly after Parrigiano, as the Twelve Apostles; St. John in the Wilderness; the Martyrdom of St. Peter and St. Paul; St. Cerf in the Temple; and others; among his etchings is one of Regulus in the Cask, after Giulio Romano.

(Vasari, Vite de' Pittori, &c.; Bartch, Peintre-Graveur; Maglier, Almanach des Artistes; &c.; Tristerni, Lexicon.)

Tretosternon, fossil genus of Cheloniidae from Tiliax forest. (Owen.)

Trevisi, or Trevisi, Girolamo da, born at Treviri in 1568, was a pupil of the son of the painter Pietro Maria Faccacchi, who was doubtless his son's instructor in the art. Girolamo, however, not wholly satisfied with the accuracy of the Venetian painters, became an imitator of the style of Raphael, and continued to a considerable extent the qualities of both schools. He lived some time in Bologna, where he painted some excellent works, especially from the story of Saint Antonio of Padua, in oil, in the cathedral. He left Bologna in consequence of the superior fame of Petronio del Vaga, then at Bologna. After painting several works in Venice, Trent, and some other places, he came to England and entered the service of Henry VIII., who employed him as architect and engineer, with a fixed salary of nearly 100L per annum. He was engaged in the capacity of engineer in the year 1544 before Bolesmghe, and was there killed by a cannon-shot, in his 36th year. There are some excellent portraits by Girolamo; they are well coloured and in an elaborate but broad manner, much in the style of the portraits by Raphael: there is a fine specimen in the Colonna palace in Rome; it is a length of a man, and is the picturesque costume of the period, holding a ring or sigaret in his hand. There are or were other pictures by Girolamo in this palace. A picture of the Madonna with various saints, which, according to Elsheimer, was painted by Girolamo, is now in the collection of Mr. Soely, in London: it was formerly in the church of San Domenico at Bologna.

There was an earlier painter called Girolamo da Treviri by whom there are still works bearing dates from 1470 to 1492: his surname according to Federici was Aviano. (Vasari, Vite de' Pittori, &c.; Ridolfi, Vite, &c.; Lanzini, Storia Piorni; TricarpeLites, a genus of fossil fruits from Shepp.

(Bowerbank.)

Trichomanes, a genus of ferae belonging to the sub-order Hymenophylaceae. These are on an elongated diliform receptacle with a cup-shaped involucre of the same texture with the frond. T. speciem is the only British species. It is extremely rare, and very beautiful. It is found in mosses, moor, and sea weeds. In texture as well as in scent it resembles some of the marine algae, and it is found to assume the samelike appearance when immersed in water after being kept perfect for a long time. It is found at Kilnarmy, Wicklow, and Toghill in Ireland, in great beauty. The soil which seems to suit it best is a mixture of loam and sand, interspersed with pieces of turf. (Newman, British Ferns; Bebbington, Manual of British Botany.)

Trichoneima, a genus of plants belonging to the
natural order Irideae. It has a regular 6-cleft perianth, with spreading segments. The 3 stigmas are bad, the lobes slender. T. columnae is the only British species; it has a solitary flower-like structure, capsular scenery, fibrous compressed leaves, the length longer than the tube of the corolla, the style shorter than the stamens. The flower is pale purple or violet, with a yellow centre. It is found in sandy places in Jersey and Guernsey. (Manual.)

TRIENTALIS, a genus of plants belonging to the natural order Primulaceae. It has a 7-parted calyx, a rotate 7-parted corolla, and 7 stamens inserted at the base of the corolla. The flowers are many-seeded, opening with a revolute fugacious valves. The seeds are invested with a reticulated tunic. T. Europaea has oblong obovate oblong leaves, a stem from 4 to 6 inches high, with the leaves mostly at the top. The flowers are on short peduncles, white, with a yellow ring. The valves of the capsules soon fall off. It is native of England and the Highlands of Scotland. (Babington, Manual.)

TRIGLA, a genus of Acanthopterygian osseous fishes, popularly known as Gurnards, and belonging to the family Loricarii in the arrangement of Cuvier. The head of Tria is mailed and angular; the opercle and almost the whole of the body is scaly; there are two distinct dorsal fins; beneath the pectorals are three detached rays; the branchiostegous membrane has seven rays, both sides; and in the front of the opercle is a spine with fine velvety teeth. The gurnards are fishes always remarkable for singularity of form, and often for brilliancy of coloring. They derive their popular appellation from a gurnard, which is the name by which they are known out of the water. In the British seas the commonest species are the grey gurnard (Trigla Gurnhardus), a silvery grey fish more or less clouded with brown and speckled with black; the red gurnard (Trigla Pinnis), of a bright rose-red colour; and the sapphire gurnard (Trigla Hirundo), a large and handsome fish remarkable for the vivid green and blue hues of the inner surface of its large pectoral fins. The two last are most abundant in the British seas. Several other rarer species are also inhabitants of the British seas. There are some beautiful small species in the Mediterranean, which also lives the flying-gurnard (Dactylopterus volitans), which differs generally from Trigla in having the fin-rays of the pectoral connected by membranes, by means of which the fish is enabled to support itself for some time in the air in the manner of the flying-fish. It is a handsome species, above a foot long. Another flying-gurnard (Dactylopterus Orientalis) lives in the Indian Ocean.

TRIGYPS. (Civil Architecture, P. C.)

TRIGONOCARPUM, a genus of Monocotyledonous fossil fruits in the coal formation of England. (Brongnart.)

TRILLIUM, a genus of plants belonging to the natural order Scrophulariaceae. It has three leaves, three flowers, and three sepal stigmas. The flower is inferior and 3-celled, the cells many-seeded. T. erectum has a large prunus-like rhizoma with thick horizontal fibres. The stem is about a foot in height, and sheathed at the base. The leaves large, acuminate, and secalis. The peduncle about half as long as the leaves, inclining to one side. The flower is large and of a dark purple. (Lindley, Flowering Plants.)

TRINCLUS, a large and remarkable group of Triodites chiefly or wholly found in the lower Silurian strata of England. (Lyell.)

TRIODIA, a genus of plants belonging to the tribe Aventinae. The glumes are from 2 to 3 flowers; the outer rachis, smooth, rounded on the back, biform with an obtuse rounded point sometimes becoming the base of a keeled awn. T. decumbens has a racemose panicule, few oval spikelets, the flowers scarcely extending beyond the glumes, without awns. The leaves flat, sheaths rather hairy. Ligule rounded, ciliate. The glumes smooth, coriaceous, and glabrous, and hiding the flower. It is found in mountain pastures in Great Britain. (Babington, Manual.)

TRIODON, a genus of plants belonging to the natural order Caprifolium. It has a calyx, with an ovate tube and a 5-parted permanent limb, with linear lanceolate permanent lobes. The corolla is tubular, almost equally 3-lobed, gibbous at the base, and longer in the calyx, and the lobes are connate and included; the stamens oblong and thick; the corolla coriaceous, obvoluta triquetrous, crowned by the calyx, 3-celled, and 3-seeded. The species are permanent herbs, rarely suffrutescent.

TRIOXANTEM. (Fever-wort, a erect hairy fimbriate round stem from one to four feet high. The leaves opposite, the pairs crossing each other, ovate, lanceolate, acuminate, entire, rather flat, abruptly narrowed into the petiole; the flowers of several kinds, white, or yellow, or red, the filaments oblong, the anthers oblong, as are the ovary, the ovules numerous. In America, in the United States, on real rocky grounds, particularly in limestone soil.

The species of Tricranium will grow in almost any kind of soil, although they prefer a vegetable or peat mould, and they are easily propagated by dividing at the root or by seeds, which generally ripen in abundance.

TRISETUM, a genus of grasses belonging to the tribe Aveninae. It has crowded spikelets. Glumes from 2 to 6 flowered. The outer palea with falcate lateral nerves, ending in acute teeth, armed. The anthers, dorsal, keeled, and twisted. The ovary red. The glumes acute and long-haired. The flowers yellowish. The upper glume oblong, lanceolate, acuminate. The floral axis hairy. It is found in fields in Great Britain. (Babington, Manual.)

TRICHODORIS, a group of fossil Crinoidae (Portlock), from the Silurian strata of Tyrone.

TRICHOSANS are in Scotland, on the northern declivities of Ben Venn, on the southern outskirts of Loch Katrine. They constitute a landscape of a very peculiar kind; for about two miles in length the surface of the ground presents the greatest imaginable irregularity, consisting of a succession of ravines, depressions, and hillocks of trifoliate, and dense and unsheltered, ranging between 200 and 400 feet. The whole is overgrown with bushes or trees, and constitutes the most complete maze which can be conceived. The paths which traverse this tract turn and twist at every step, and present a different aspect to the traveler. The individual who first enters the district is wholly lost. The veller finds himself almost at every minute in a country which has totally changed its aspect, and presents quite different objects from those which met his eyes a few moments before. It has 3 coloured flowers, and this is the only species of this tract, favoured, in the last century, the illicit distillery of whiskey; but it is stated that, at present, this trade has entirely ceased.

TROUGHTON, EDWARD, the first astronomical instrument maker of our day, was born October 1753, and died at his house in Fleet Street, June 12, 1835. He came of a family of respectable yeomen, and was placed in the firm of his uncle and brother, who were carried on business as mathematical instrument makers. In 1782 the Troughtons established themselves in Fleet Street; in 1826 Edward Troughton, then the sole survivor, took Mr. Mathias into partnership. There is a full memoir of Troughton in the monthly notices of the 'Astronomical Society,' vol. iii. p. 149. A handsome subscription bust, by Chantrey, is in the Observatory at Greenwich, and the latter being the last of the genus, when he was nearly deaf, only hearing by the help of a powerful trumpet; and he never could distinguish colours otherwise than by their brightness,—a ripe cherry and its leaf were to him of the same nature. The larger astronomical instruments are not the facsimiles of one another, which the smaller and more universal ones are: any more than the great architectural displays of a large city are of the same kind, in such a place as Paris, distant to one and the same degree, the houses of one of the same street. Each one has its own difficulties, its own objects, and its own way of overcoming the
first to meet the second. The great works of Troughton are as well known in the astronomical world as those of Wren in the physical; and he also gave himself to all the minor branches of his business, and of his it may be said with truth that he improved and extended every instrument he touched, and that every astronomical instrument in its turn the subject of his attention. 'The instruments which facilitate navigation were peculiarly objects of interest to Mr. Troughton: and long after his infirmities were an effectual bar to the application of his most esteemed friends, he exerted himself to supply the seamen with well-adjusted and accurate sextants.' The articles on astronomical instruments in this work contain frequent references to Troughton's improvements. He wrote one or two articles in the 'Philosophical Transactions' and several in Brewster's 'Cyclopaedia,' references to which will be found in the memoir cited.

TROUS DE LOUP, in the military art, are pits dug in the ground in the form of inverted cones or pyramids, in order to serve as obstacles to the advance of an enemy: each is made about 8 feet in diameter, or in breadth, and as many in depth, and a pointed stake is planted upright in the bottom. The pits should be disposed chequerwise in two or three rows, their centres being at distances of about 10 feet from one another; and their sides should have such a slope that the enemy's riflemen, should they attempt to occupy them, must be concealed in them from the view of the troops whose pits they protect.

The earth obtained from the excavations should be formed into a sort of glaciés within the line of pits in order that the enemy may not use it to fill them. The Trous de loup are generally formed before the salient points of field-works or in the intervals between them; and they are sometimes executed in rear of such works in order to protect the gorges when the latter are without parapets.

TRYPHONINUS, CLAUDIUS, a Roman jurist who lived under Septimius Severus and his son Antoninus Caracalla. He wrote notes on the works of Cervidius Secundus, and to this last known book of Disputations, from which there are excerpts in the Digest. There is a rescript of Antoninus to him (Cod. 1, tit. 9, s. 1), but whether in his capacity of governor of Syria or as the agent of the Fiscus is uncertain. He is cited once by Paulus.

TUNNY. [ThYNNUS, P. C. S.]

TYLOPHORA (from τρύγος, a swelling, and the root φορά, to bear, in reference to the ventricose pollen masses), a genus of plants belonging to the natural order Asclepiadeae. It has a rotative 5-parted corolla, the corona 5-leaved, the levula simple and flabby. The style is terminal, on a membrane; the pollen masses erect, fixed by the base, with simple margins, transverse or ascending, minute and ventricose. The follicles smooth, tapering to the point, compressed, and somewhat angular on one side. The species are twining herbs or subshrubs. The leaves opposite, membranaceous, and flat. The flowers usually small.

TYPHA, a genus of plants belonging to the natural order Aridieae and the suborder Lemnese. The sterile and fertile spikes are cylindrical. The sterile is surrounded with setae. The three anthers on one filament; the ovary surrounded with setae, at length stalked.

TULIFLORA, great Reed-mace, has a stem from six to seven feet high; linear leaves, nearly sessile, the sterile and fertile cactins contiguous and very long. The leaves very broad and overlapping the inflorescence. It is found in ponds and lakes in Great Britain. (Babington, Manual.)

TYPHUS, a form of fever, in which low nervous symptoms predominate. The following are its principal features:

- It has a slow and insidious origin, lasting from fourteen to twenty-eight days. It is attended during the principal part of its course with symptoms of depression and exhausted nervous power, with feeble pulse, great muscular weakness, and low delirium.
- There is a dry, rough, dark tongue, black sores on the teeth and gums, and general fustor of the body. It is capable of being propagated by the contagious emanations from the person affected. This is the low nervous or typhoid fever of this country. For an account of fever and its distinctions, see Fever, P. C.; Strobes, P. C. S.

UDAL TENURE. [Sheetsands, P. C., p. 385.]

UDOTEA. A species small from Bridlington is referred to this genus by Mr. J. E. Lee.

ULÖNDRON, one generic division of the great group of Lepidodendron families of plants which occur in the coal formations.

UNDULATORY THEORY OF LIGHT. This subject has been already treated briefly, under the same designation; and for further notices concerning its principles, as well as for its applications explanatory of the remarkable phenomena of light, the reader is referred to Dissection, and to Polarization of Light (P.C.), also to the following articles, which have been introduced in this Supplement: Circular Polarization; Colours of Flames; Elliptical Polarization; Polarization, Movements; Polarized Rays; Swiftest Propagation, Principle of; and Vibrations of Light.

UNION OF ESTATES. [Merer, P. C.]

UNITED STATES OF NORTH AMERICA. Since the article Oregon Question, P. C. S., was written the dispute concerning the Oregon territory has been settled. On the 28th of June, 1846, Sir Robert Peel, in the speech in which he announced his resignation of office, informed the House of Commons that the British government had offered a convention to the government of the United States, of which the President of the United States, on the 13th of June, 1846, announced the acceptance by the American government, without the addition or alteration of a single word. The first proposal of the British government was as follows:

'That from the point in the 49th parallel of N. lat. in which the boundary laid down by existing treaties between Great Britain and the United States terminates, the line of boundary between the territories of the two countries shall be continued westward along the 49th parallel to the middle of the channel which separates the continent from Vancouver's Island, and thence southerly through the middle of the said channel and the Fraca Straits to the Pacific Ocean. Provided the navigation of the channel and straits, south of the 49th parallel, shall be free and open to both parties.'

This leaves to the British the whole of Vancouver's Island, with equal rights of navigation in the Straits. The second proposal was:

'That from the point at which the 49th parallel of N. lat. intersects the great northern branch of the Columbia river, the navigation of the said branch shall be free and open to the Hudson's Bay Company, and for all British subjects trading with the same, to the point where the said branch meets the main stream of the Columbia, and thence down the said main stream to the ocean, with free access into and through the said river or rivers; all the usual portages along the line thus described to be free and open to both parties. Provided that in navigating the said river British subjects shall be on the same footing as those of the United States: it being always understood however, that nothing herein shall be considered as preventing the government of the United States from making any regulations as to navigation of the river not inconsistent with the present convention.'

The circumstances under which Texas has been annexed to the Union are stated under Texas, P. C. S.

Michigan, described as a territory in P.C., was admitted into the Union as a State at the end of 1835. The Governor is elected for two years, and his salary is fixed at present at $1,500 dollars per annum. The Senate consists of 18 members, elected for two years; the House of Representatives of 63 members, elected annually. The pay of the members is three dollars a day during the session. The seat of government is at Detroit, or wherever the legislature shall direct, till 1847, when it is to be established permanently. The legal establishments are, a Court of Chancery, a Supreme Court, Circuit Courts, and a District Criminal Court. The Chancellor has a salary of $1500 dollars, and there are five Chancery Circuits. In the Supreme Court there is a Chief Justice, with a salary of $1600 dollars, and three associate Justices with salaries of $1500 dollars each. The four Judges of this court are appointed by the Governor, with the advice and consent of the Senate, for a term of seven years. In 1845 the main institution of the State has 78,000 students, and 12 preparatory schools, at Tecumseh, Rome, Kalamazoo, White Pine, and Ann Arbor, about 1200 students. The professors were:—Greeley and Roman Language; 2, Mathematics; 3, Moral and Mental Philosophy; 4, Geology and Mineralogy; 5, Botany and Geology. In 1844 the number of scholars in the Common Schools was 66,818, and the amount appropriated from the state treasury among the several districts was $28,063 dollars. Michigan is thought, both as to the means of education and the success of the system pursued, to be little behind the most forward of the eastern States. The State prison at Jackson is constructed on the Auburn plan. The Central Railroad runs from Detroit to Marshall, 110 miles, and 36 miles more of the road were expected to be completed by the end of 1846. The Southern Railroad runs from Monroe to Hillsdale, 68 miles. The population of Michigan in 1830 was 31,639; in 1840 it was 212,267. There are no slaves. Florida was admitted into the Union as a State in 1845, the first Governor having entered upon his office in October of that year. The Governor is elected for four years, the Senators for two years, the Representatives for one year. The number of Representatives is never to exceed 60. The Judges of the Supreme Court are to be elected by a concurrent vote of both Houses, at first for five years, and after that according to good behaviour. The right of voting is to belong to every free white male, aged 21 or upwards, who has resided in Florida two years, and six months in the county in which he votes, and who shall be enrolled in the militia or by law exempt from serving therein. No laws are to be passed to encourage immigration of persons bringing slaves with them. The General Assembly may prevent free colored persons from entering the State. The population in 1830 was 54,730; in 1840 it was 54,477, of whom 28,717 were slaves. (American Almanac, 1837, 1845, 1846.)

V.

VACHHELLA, a genus of plants belonging to the natural order Leguminosae, contains the only 5-toothed; the corolla tubular, genopetalous, and 5-toothed. The stamens are numerous and distinct; the legume cylindrical and turpiz, scarcely dehiscing, filled with pulp, and a dark brown, and set with 

V. Fertznitiana is a native of the East and West Indies and Africa. It is a large shrub or small tree, with straight sharp thorns. The leaves are bipinnate, the leaflets linear and nearly glabrous; the peduncles and pedicles more or less hairy; the flowers capital, the heads globular, 2 or 3 together, each on an axillary peduncle. The bark exudes a considerable quantity of gum. The flowers when distilled yield a delicious perfume.

(Lindley. Flora Medica.)

VAILLANT, WALLENT, a very distinguished portrait painter, was born at Lille in 1625, and was the pupil of Franscisco Queslinus, at Antwerp. He painted the portrait of the Emperor Leopold I. at Frankfort, and many of the people of his court. He subsequently went with Marshal Grammont to Paris, where he was equally esteemed by the French court. After having amassed considerable riches he died at Amsterdam, in 1677. Vaillant was employed in 1685 at Brussels by Prince Rupert to paint the portraits of some persons in the new mode of mosaic into engraving then communicated to the Prince by Siegen. (Siegen, Leopold van den, P. C.S.) As Vaillant is the first artist who engraved in this style, his prints have more than ordinary interest. Among these are two portraits of Prince Rupert, one of which is inscribed—Prima Roberi, vinder van de Swarte Prent Konst, which is one of the principal causes of Siegen's being so long deprived of the merit of his invention.

Vaillant had four younger brothers, who were all painters or engravers and his pupils.

(Deseupe, Vues des Peintres Flamands, etc.; De Laboisse, Histoire de la Gravure en Monique Noire.)

VALENS, ABURNUS, a Roman jurist, whose age is partly determined by the fact that he cites Jovannus and Julius (Dig. 4, tit. 4, s. 33), from which we may conclude that he was younger than both. He is called Aburinus in the Florentine Pandect. He was a Sabian, as appears by his being placed by Pomponius among the followers of Jovannus. It appears that he was living under Antoninus Pius (Capitol., Pac. 193). The same is also the case of Capistrani, stands, he is called Salvis Valens. His complete name may have been Salvis Aburinus Valens; or Salvis in this passage may be separated from Valens and may mean Salvis Julianus. But there is a rescript of Flavius (Dig. 48, tit. 2, s. 7, 8) addressed to Salvis Valens.

Valens wrote seven books on Fideicommisina, from which there are excerpts in the Digest; and there is also in the Digest a passage from the seventh book of a work on Actions. Valens is mentioned by Pomponius, and cited several times by Paulus (Dig. 4, tit. 4, s. 33). VALESSOR. [VAYASOR, P.C.]

VAN, or VAN. [VANERSS, P.C., p. 360.]

VAN HOECK, JAN, a distinguished Flemish painter, was born at Antwerp about 1600. He first studied for one of the learned professions, but became the pupil of Rubens, and studied upwards of some time in Rome. While in Italy he was invited by the Emperor Ferdinand II. to his court, and was much employed by him. He eventually returned to his own country, where he died, according to Houbraken, in 1650.

Van Hoeck was admirable in history and portrait, and excelled both in light and shade and colour; his figures are also beautiful, but is than is the case with those of the pupils of Rubens and the Flemish school generally. The Christ on the Cross in the church of Saint-Sauveur, or the cathedral, at Bruges, is one of the finest pictures in Belgium. The Christ, which is one of the size of life, has extraordinary effect and reality, and is certainly superior to the celebrated Christ of the church of St. Michael, at Ghent, by Vandyck, and it is more real and impressive than any of those of Rubens: beneath the cross are the Virgin and other saints. There is a print of it by the younger Cornelius Galles: this engraver however is not very accurate in his drawing. Independent of the Christ, the composition of the picture is meagre and formal, and wants dramatic truth.

VARIATION OF PARAMETERS. A parameter was a name originally given to a particular line, plane, or cone section: being the third proportional to a diameter and its conjugate. In time the word was applied to any line which serves by its value to distinguish, or to help to distinguish, one individual of a family of curves from another: thus the radius of a circle, the axes of an ellipse, the co-ordinates of the centre of either, were called parameters. When a word gets into the descriptive name of a method, it may happen, as part of a phrase, to outlive its own separate use: and such has been the case with the word parameter. As this word is now generally abandoned, and element is the most frequent substitute for it, it would be desirable to speak of variation of elements.

Whatever phrase we may use, the thing occurs both in physics and mathematics, in modes which are closely connected with each other. A planet moves in a curve which is not an ellipse, but which should change and become an ellipse if the disturbing attractions of the other planets were removed, and that of the sun only continued. The easiest way of calculating the planet's motion is to consider the planet as moving in this ellipse, while during the motion the elements which determine the ellipse are perpetually changing: so that the form and position of the ellipse both vary. This is done in such manner that the ellipse of each moment is that which the planet would go on to move in, if at that moment the disturbing attractions were all removed. The advantage is that in this case the elements will vary very slowly, or it will be long before the disturbing attractions produce much effect. In theory, any curve might be taken. A planet for instance might be supposed to move in a parabola, which varies its dimensions and position in a manner to be determined.

In TROCHOIDAL CURVES, P. C., all the curves given are produced by a point moving in a circle with variable elements; that is, of variable centre, though given radius. If it were required to investigate trochoidal curves with loops and undulations of different magnitudes, the best way would be to consider them as made in the same manner, with a circle of variable radius also: or else to make both circles variable.

In the differential calculus the variation of elements is introduced thus: — an algebraical expression containing some variables and some constant elements be proper to answer a certain purpose, it is not impossible that it may answer the same purpose when the constants are made variable, provided they are made to vary in a proper manner. Now, if the purpose which is to be answered involve differentiation, the infinity of the number of suppositions which may be made as to the variation of the (former) constants is equivalent to introducing an arbitrary function instead of each constant, to be determined by the conditions of the question. Two species of cases have frequently arisen.

1. When under certain circumstances a problem is solved by an expression containing certain constants, and the circumstances are then altered; it is often convenient to inquire whether the altered problem might not be solved by the same expression, on the supposition that the constants become variable. And the question then is, how the (former) constants are to be made to vary.

2. Without any alteration of the circumstances, having a solution which contains constants, it may be asked how to make arbitrary variables in place of constants, so that the altered expression may still be a solution.

In both cases it is obvious that as soon as the constants are made variable there is introduced some effect of all expressions into which they enter will receive an accession of terms above what they had before. These new terms, which we may describe as functions of the variations of the elements, must, in the first case at least, be taken as to provide for the effect of the altered circumstances. But in the second case they must destroy one another's effects altogether. We shall take a few instances in which the variation of elements is successful or unsuccessful.

P. C. S., No. 172

Vol. 11. 4 T
1. The equation \( y^2 + Py = 0 \), P being a function of \( x \), is solved by
\[
y = \sqrt{\frac{C}{P}} + \frac{P}{2} \] 
C being a constant. Now alter the equation into \( y^2 + Py = Q \), and to meet the alteration, let \( C \) be a function of \( x \). On this supposition \( y^2 + Py \) becomes
\[
-CP^2 \sqrt{\frac{C}{P}} + C \frac{P}{2} \sqrt{\frac{C}{P}} + Q \] 
But this ought to be \( Q \); therefore we must have
\[
C \sqrt{\frac{C}{P}} = \frac{Q}{C} \] 
and \( C \) being another constant. Here \( y^2 + Py = Q \) is solved by \( y^2 + Py = 0 \) and subsequent variation of an element.

Now try \( y^2 + Py = 0 \) and \( y^2 - Py = Q \) in the same manner. The first is solved by \( y = \pm (x + C) \) and if \( C \) be made variable, and \( y \) thus altered be introduced into the second, it is found, making \( x + C = C \), to require the solution of
\[
x^2 + Q \sqrt{Q} = 0
\]
as difficult an equation as the original. In this case we are unsuccessful.

2. Let \( \frac{du}{dy} = x \). One solution of this is \( u = \frac{1}{2}x^2 + \frac{a}{x} + \frac{b}{x} \).

The above solution is thus a function of \( a \) as constant and \( b \) as constant. To find a more general solution of this equation let \( b \) be a function of \( a \) as a function of \( x \) and \( y \).

We have then
\[
\frac{du}{dy} = \frac{dx}{dy} + \frac{dy}{dx} \] 
and the equation will obviously still be satisfied if \( a \) and \( b \) be so related that
\[
x + \frac{dy}{dx} = 0
\]
where \( a \) is what function of \( x \) we please, so also is \( db \).

It is followed that if \( y = \phi(x) \), and \( x = f(y) \), we may make \( a \) what function of \( x \) and \( y \) we please. Let \( a = \phi(x) \) and \( b = f(y) \).

We have then
\[
u = \frac{1}{2}x^2 + \phi(x).
\]

This subject has many developments. We have introduced it here under the idea that some students of the differential calculus may be led to consider it at an earlier period of their reading than would otherwise give it to them. It is to be remarked that this method does not merely search for some solutions of a question; if the number of constants be sufficient, it goes direct to the most general solution. Now in the first example, the function of \( x \) what is capable of being represented by \( C \sqrt{\frac{C}{P}} \); in our third there is no function of \( x \) and \( y \) so that the complete solution is
\[
u = \frac{1}{2}x^2 + \phi(x).
\]

Vegetable morphology, or Metamorphosis, is that department of science which contemplates the laws which regulate the forms of plants and of their particular parts. In the earlier period of the history of botany plants were studied as individuals or groups of individuals, without any reference to the general laws which governed either the external or the internal forms of plants, or those which influenced the production of various forms in the same individual at different periods of its existence, or of the same species under varying circumstances.

Linnæus, although he never made any practical application of his idea, seems to have been the first to have suspected that the varied forms of the flowering organs, and even other appendages of the axis of the plant, were modifications of the leaf. In his 'Philosophia Botanica' he has the following remarkable passage:—The origin of the flowers and the leaves is the same; the origin of the buds and the leaves is the same: the bud consists of the rudiments of the leaves; the flower comes from the rudiments of the leaves united. Although the doctrine of metamorphosis is a limited one; and was thus畅销ly proclaimed by the German Linneus, and many facts pointed out by him to prove its truth, yet little or no notice was taken of this department of science by his followers. The next great botanist, who drew attention to this subject, was not, and apparently quite independent of Linnæus, was not a botanist, but a poet. Goethe frequently occupied himself with natural history studies; and in one of his letters, dated 1768, mentions several of his friends who were botanists, among whom he distinctly stated that every part of the plant is the reproduction of a primitive type.

This was followed by a paper on the subject, in which he clearly points out the importance of this idea in the unfolding of a primitive type. At the time these papers were published they were read with the same as the fictions of a poet rather than the sober realities of science. In Great Britain they found little favour, but were quietly thought over by Robert Brown, who, by a series of accurate observations demonstrated the practice of this doctrine in the morphology of numerous species of the various families of plants. The idea of Goethe was also adopted by De Candolle, in his doctrine of a primitive type among plants, from which all departed by the decrease, increase, and subordination of their organs. In this way the idea that morphology has more or less influenced the greatest botanical observers of the present day, and it assumes a position as the first importance in botanical inquiries.

Morphology may be divided into two great divisions. First, that which treats of the forms of plants and their organs in general, and which is only concerned with a few of those general forms which are found common to all plants; and secondly, that which treats of the forms of particular groups of plants and of individual organs. This latter department is of the utmost importance, and is that which contributes so greatly to the just apprehension of the relations which exist between the various groups of plants and their organs. It may be divided into two parts, one of which regards the external form of the plant, as resulting from the combination of the various tissues into organs; the other regards the internal form which the various tissues of the plant assume.

There are certain general principles in morphology which have been well established, and one of these is, that the organs of plants in the Penny Cyclopaedia, and that every plant, has an ascending and descending axis; the former of which is called the stem (Exoecous, P. C.; Exoecous, P. C.), and is the latter the root (Rooy, P. C.). They may be traced downwards or upwards through the various series of plants; downwards till we arrive at a point where the cells exhibit a tendency to either an ascending or descending growth, as in the cells of Protococcus; or upwards till the increasing development of the stem exists in the most complicated variety of forms. It is in the latter or higher groups of plants that the laws of morphology have been studied with greatest attention, and have led to the belief that its only application existed in the series of changes which the leaf of the higher plants undergoes in its conversion into the parts of the flower and the fruit. It is from this department of botany that the most convincing illustrations of the truth of the laws of morphology may be drawn, and it is here that the most obvious practical applications of them may be made; but form does not more distinctly distinguish the higher than the lower plants, and in many of the phenomena of the latter morphology as a natural law may be applied as to the highest plants.

The leaf however affords the best illustration of the nature of morphological laws. This organ may be regarded as a theoretical type on which the other organs are formed, and from which they are
VENUS

supposed to have departed. In support of this theory we have the fact, that all the organs of the axis may be traced by insensible gradation either to or from the leaf. Thus the bract is often undistinguishable from the leaf, the sepals from the petals, the petals from the stamens and from the carpels, the carpels from the leaves, and the ovules from leaf-buds. This is the series of gradations which prove the positions of morphology. When these gradations take place, as they usually do from nature, the leaf in the internal organs of the flower, it is called an ascending metamorphosis; when it takes place from the central organs of the flower to the leaf, it is called a descending metamorphosis. This latter phenomenon has often presented many variations and such changes are called monsters. Most of the double flowers of our gardens are the result of a descending metamorphosis, in which petals are developed instead of stamens. As an instance of organs which have not assumed the development of leaves, but which yet are formed on the same type and obey the same laws, we may name the stigmas and scales of leaf-buds.

The result of these facts is that we may regard the flower as a collection of leaves arranged in whorls, and in fact a branch with a short axis. This idea explains at once those apparently anomalous occurrences where branches grow out of the fruit of the pomegranate, or the apple. The apple does not represent the growing point of a branch, which, if the circumstances no longer exist which produced the peculiar leaves from which it is formed, will take on the ordinary growth of a fruit. The apple with its sepals and its petals is the expression of certain laws which regulate the growth of the flowers and fruits of plants, and which, being applied to their peculiarities, are the best means of securing a natural classification.

VENUS. [From Venus, the Roman goddess of Love.]

VELLA. (Latinalised from Velo, the Celtic name of the crest,) a genus of plants belonging to the natural order Crucifereae. It has an ovate pouch, with a dilated winged leafy flat style, longer than the convex valve. The flowers are yellow, and are, as well as the pod, erect.

V. amara was found in the island of Ray on Salisbury plain, but has not since been noticed. It has double pinnatifid leaves, and is a native of Spain; it has yellow petals with long dark purple claws; the larger stamens are conic by pairs; the seeds two in each pod.

This shrub, though generally kept in a greenhouse, is sufficiently hardy to live during the winter in the border in a warm aspect. Young cuttings will strike root in sand under a glass.

(Don, Gardner's Dictionary; Babington, Manual of British Botany.)

VENUS INSPIECIENDA, WRIT DE. When a woman is suspected to have begotten herself with child in order to produce a supposititious heir to the estate, the heir presumptive may have a writ de ventre inspeciendo, to examine whether she be with child or not; and, if she be, to keep her under protection until it is safely brought to term, and to submit it to the practice of the civil law: but if the widow be, upon due examination, found not to be pregnant, the presumptive heir shall be admitted to the inheritance, though he hath to look to another, on whose behalf years have been spent from the death of a husband! (Blackstone, Comm. i. 456.) The Roman practice is explained in the Title of the Digest (25 tit. 47) as being necessary in cases of bastardy and infanticide. This title contains a Reciscript of Ausilius and a case in which a woman denied her pregnancy and the husband maintained it. The wife had separated from the husband, and the child was born in the same house, though by law it would belong to the husband. If a woman alleged that she was left pregnant by her deceased husband, it was her duty to announce the fact to those whom it concerned, and to inform them that they might, if they pleased, send women to inspect her (que ventrum inpectant). All the proceedings of inspection and of watching the woman, if she should be reported to be with child, are minutely described in the Praetor's Edict. The penalty in case of the woman not complying with the Edict was, that the Praetor would refuse to the child the bonorum possessionem.

The form of the English writ de Ventre Inspeciendo is given Co. Litt. 8 b. It is directed to the sheriff, and commands him to try the jury of twelve for the county whether the woman is with child, or whether she be ensnare. If they find that she is with child, another writ issues, which commands her to be safely kept and duly inspected by the women, who must be present at the delivery. Tracton is the writer by whom this work is first mentioned.

The use of this writ is an instance in which what is called a proceeding at common law is taken from the Roman system. The writ is not obsolete, as some people suppose; it has issued within the last few years. (Co. Litt. 8 b. and N. 44 in Butler's edition; Comyns, Digest, Bastard, C.)

VERMELIUS. [From Vermilion, P. C. S.]

VERMIGLI, PIETRO MARTIRE, born in Florence in 1500, studied for the church, and entered early the Order of the Regular Canons of St. Augustine; in which he became distinguished for his learning, and rose to offices of trust. Being at Naples he became acquainted with John Valdes, a Spaniard, who had been a convert to the doctrines of the Reformation. Vermigil adopted some of those tenets, but still returned to his Order. The Erastians of Wittenberg sent him to the University of Louca, as prior of San Frediano, he there publicly avowed his new doctrine, and was soon after compelled to fly to Switzerland, in 1542. He thence went to Strasburg, where he became the Convertor. The Duke of Wurtemberg, on the invitation of Bishop Cranmer, he repaired to England, where he was graciously received by King Edward VI. and was appointed Lecturer upon the Holy Scriptures at Oxford, where he met with much opposition, from the heads of colleges and the higher graduates, and ran some personal risk. In 1553, after the accession of Queen Mary, being obliged to leave England, he returned to Strasburg, where he resumed his chair as Professor of Divinity, and became an Aristotelian philosopher. In 1566 he was invited by the senate of Zurich to fill the chair of theology in that University, which he accepted. In 1561 he repaired, with other Protestant divines, to the conference of Passy, in France. In the following year Vermigli died at Zurich, much regretted. He wrote on dogmatic and ethical subjects, commentaries on parts of the Scripture, besides numerous epistles to 'His Brethren of the Protestant church of Louca,' to the Protestant churches in Poland, to the English church, to Calvin, Bullinger, Beza, Melanchthon, and other reformers, to Queen Elizabeth, and to several English prelates and noblemen. His works were translated from the Latin into English. The Common Places of the most famous and renowned Divine Doctor Peter Martyr, divided into four principal parts by Anthony Marten, translated and published in 1645, under a biography of Vermigli by Josias Simler, of Zurich: this collection contains a complete course of Christian ethics, and may be read with advantage now.

VERNET, ANTOINE CHARLES HORACE, commonly called Carle Vernet, a French historical, genre, and battle painter, was born at Bordeaux, August 14, 1758, and was the pupil of his father, Claude Joseph Vernet, the celebrated marine and landscape painter. He entered the French Academy at Paris, where he gained the second prize for painting when in his eighteenth year, and in 1782, six years afterwards, he obtained the grand prize. With it the privilege of studying for a certain period in the French academy at Rome. In 1787 he was elected a member of the French Royal Academy of Painting and Sculpture. He was a pupil of Paul Aemilius, and he was subsequently, after the remodeling of the academy, nominated a member of the Institute of France.

His principal works are—the large picture of the Battle of Marengo, and a battle against the Mamelukes, exhibited in 1804; the Morning of the Battle of Austerlitz, with the Emperor giving orders to his Marshals, and an equestrian portrait of Napoleon, in 1808; the Bombardment of Madrid,
In common or white light, the vibrations of the refrangible molecules may be conceived to take place in any manner, but in the case of red light, French observers have observed that they are affected by the transverse vibrations only, or those which take place in planes perpendicular to the direction of the motion of the wave or ray, the vibrations in this direction, if they exist, are of very small magnitude. The hypothesis is supported by experiments made on a pencil of light which, after diverging from a radiant point, is reflected from two mirrors inclined to one another at a very obtuse angle, and transmitted through the air, if the two mirrors are having a great refracting angle, so as to proceed as if it formed two pencils diverging from different points; the reflected or refracted waves are found to interfere with one another so that the least possible number of maxima or minima are produced bright; but when two plates of tourmaline having their axes at right angles to one another, which consequently polarize the light in planes at right angles to one another, are placed in the directions of the waves reflected from the two mirrors or transmitted through two faces of the prism, the waves cease to interfere with one another and no dark fringes are seen. It follows that no vibrations could have then taken place in the directions of the motions of the waves of the incident light which had interferences ought to have been observed in the light which was polarized as well as in that which was not so.

For the consideration of the vibrations of light, in two polars or by which circular and elliptical polarizations are produced, see Circulaire Polarisation, P. C. S.

VICTOR, CLAUDE FERRIN, Duke of Belluno and Marshal of France, Commander-in-Chief of thearmy of the Voges, on the 7th of December. 1764. He was seventeen years of age when, on the 16th of December, 1781, he enlisted as a private soldier in the 4th regiment of artillery, and it was at that time that he distinguished himself in the charge when the first events of the Revolution of 1789 occurred, but, animed with the warlike spirit which then pervaded the French nation, he again eagerily sought for military employment, and entered as a volunteer the third battalion of the Department of the Drôme. A few months suffred for this young and intrepid soldier to raise himself from the lowest rank to that of adjutant-major and chefe de batallion. With the batallion under his command he distinguished himself at Corons, by pulling the attack of three thousand Piedmontese and a regiment of emigrants. At the head of the same batallion he obtained considerable success, in 1798, at the siege of Tou- lon; under the orders of General Lapoye, he gained the important heights of Pharon, and afterwards, with similar good fortune, attacked the Fort Aiguielle, the capture of which greatly contributed to the favourable issue of the siege. These brilliant actions, in which he was twice wounded, were rewarded by his promotion to the rank of adjutant-general.

Transferred to the army of the Eastern Pyrenees, with the rank of general of brigade, he rendered himself conspicuous in his actions at the siege of Cerdans (October 20, 1794) and Romans (January 2, 1795). After the termination of the war between France and Spain by the treaty of peace signed on June 12, 1795, he was sent with the army of Italy. The courage which he displayed in the several actions of that campaign, and particularly in the action at Bergio (May 30, 1796), brought him under the favourable notice of Bonaparte, who gave him every opportunity for further distinction by entrusting him with the management of manoeuvres as honourable as they were perilous. His conduct during the subsequent engagements which took place at Ceesa- nova and Mondovi (April 6 and 18, 1798) justified the high estimation in which he was held by his chief, and were recognised by the government at Paris in a flattering letter which they sent him. The following year, by a series of skilful manœuvres, he greatly contributed to the success obtained by Massena [Massena, Marshal, P. C. S.] over the Austrian general Wurmser [Wurmser, P. C. S.] at Corona (August 11, 1797). It was on account of his successses during this campaig, of which we have enumerated a very small portion, that he was raised to the rank of general of division. In this capacity he powerfully seconded the operations directed by General Lannes against the Papal States [Lannes, P. C. S.], and after delivering the Papal States by a series of skilful movements, he joined with the troops under his command the towns of Faenza and Cesena; he afterwards marched against Ancona with a detachment of twelve hundred men, and captured it without a shot being fired from the town. On the march, he collected twenty pieces of cannon, and a garrison of five thousand de-generate Romans. 'General Victor,' says Napoleon, 'crossed
the Po at Borge Forte, at the head of four thousand infantry and six hundred horse, and formed a junction, at Bologna, with the Italian division of four thousand men, under General Lathon. 'These and three thousand Portuguese came under the command of the States of the Church.' (Montbod賽, History of the Captivity of Napoleon at St. Helena, vol. ii. p. 58.)

After the battle of Custoza, General Victor was appointed to the difficult command of the troops of the Vendée. By his skillful dispositions, and by his conciliatory, but firm and decisive conduct, he maintained the tranquillity of that country. In May, 1816, going to the army of Italy, he was placed at the head of a division. In the following year, he acquired fresh renown at the engagement of St. Lucia (March 30, 1799). Shortly after this battle he received orders to advance against Artois. The campaign was decided in favor of the French army of Naples through the valley of the Borinonde; in effecting this movement, his division was attacked by a large body of Piedmontese insurgents, in the narrow and difficult passes of those mountains; his troops however bravely repelled this attack at the point of the bayonet, and, after surrounding great dangers, he was enabled to effect a junction with the army under the command of General Macdonald.

[VIC] [Macdonald, Marshal P. C. S.] Victor bore a distinguished part in the engagement on the banks of the Trebia, which proved disastrous to the French. He was afterwards sent to Paris by General Moreau, to solicit from the Directory returns for a considerable length of time. On the fall of the commission, he returned to Italy and resumed the command of his division, which acquired fresh laurels at the battle of Bassano, where it formed part of the centre under the command of Gen. Oudinot.

At the memorable battle of Marengo, the division of Victor formed part of the advanced guard; to the bravery and perseverance which he displayed on this occasion may in a great measure be ascribed the favourable issue of this long-disputed engagement. His services were rewarded by the presentation of a sabre of honour, on which was inscribed a flattering testimonial to his merit. He was afterwards transferred to the Bavarian army, and seconded to General Marmont; his conduct in that campaign, though unmarked by any brilliant exploit, was such as to maintain the high reputation he had acquired.

After the peace of Amiens, he was sent to the court of Denmark as ambassador from the First Consul. He held this office till 1806, when, on the breaking out of the war with Prussia, he was appointed to the command of the tenth corps of the grand army. A wound, which he received at the battle of Jena, did not prevent him from directing in person the operations of the corps under his command during this short but brilliant campaign; and he powerfully contributed to the victory obtained over the combined forces of the Prussians and Russians at Pultusk (December 26, 1806). In this campaign he was taken prisoner by a body of partisans, but, by a clever stratagem, succeeded in eluding his captors.

The following year was marked by the great battle of Friedland (June 14), in which Victor, at the head of the first corps of the grand army, so greatly distinguished himself, that Napoleon, on the field of battle, raised him to the dignity of Marshal of the empire.

After the treaty of Tilsit (July 6, 1807), Marshal Victor was appointed Governor of Berlin, a government including the greater part of Prussia. This office, which he held for fifteen months, was one which afforded many temptations to an abuse of power, but he appears to have excised his authority with dignity and moderation.

In 1813 he was intrusted by Napoleon with the command of the first corps of the French army in Spain. Shortly after his arrival in that country, he obtained important advantages over the Spaniards in the engagements of Epenosa (November 10 and 11, 1813), and Sobrarbe (December 4). On the 13th of January, 1809, he routed the remnants of the Spanish army which had been defeated at Toulouse [Lannes, P. C. S.], but, which, reinforced by French and Spanish troops, had advanced towards Madrid. The intrepidity, which had taken up a menacing position at Ucles. In this engagement upwards of three hundred officers, including two generals and twelve thousand soldiers, were made prisoners; all the baggage and ammunitions, with the treasures of the monastery of Escorial, were carried off by the French. According to the Spanish accounts, this victory was stained by the exercise of wanton cruelty towards the prisoners, in retaliation for similar cruelty exercised on the French, and the looting and plundering which was committed in Spain for the benefit of the French. (Duyfker, 'History of the Peninsular War,' vol. ii. p. 16.)
When the success of the allies and the abidement of Napoleon had replaced the Bourbon dynasty on the throne, he was rewarded by his appointment to the command of the second military division. On the return of Napoleon from Elba, he issued a proclamation, in which he allowed himself to speak of the cause of his fortune in terms which reflected discredit upon his character; he describes him as 'the man who has tyrannized, desolated, and betrayed France during twelve years,' and he urges every Frenchman to pursue to the uttermost his tyrant, but 'the satellites who accompanied him on his plundering excursion.' Independently of the ingratitude which this language betrays, it evinces a singular want of discernment, coming from one who had observed the most complete instance of these sentiments. In the years that followed, he appears in the examples of Marshal Berthier (Berthier, P. C.) and Marmont assisting Louis XVIII to Ghent. [Louis XVIII, P. C.] On the second restoration, he was created a peer of France, and appointed one of the four major-generals of the royal guard. He was also, not very unfortunately as conspicuous as the president of the commission charged to inquire into the conduct of the former brethren in arms during the hundred days [Nap, Marshal, P. C. S.]; in that capacity he is reported to have displayed an unnecessary and pertinacious severity. In 1816, Marshal Victor was appointed to the command of the reserve division of France. In 1812, he was named by Louis XVIII, minister of the war department; in this capacity he altogether disappointed the expectations to which his past had given rise; he neglected the affairs of the new army as effectually as he had done those of the old, and lost the little popularity he had hitherto enjoyed. He actively promoted the expedition to Spain of 1823 [St Clair, P. C. S.], and, having returned from the mission, he accompanied the army as second in command to the Duke of Angoulême. After the revolution of 1830, [Charles X., P. C. S.] he ceased to take any active part in public affairs; though he gave his adhesion to the government of Louis-Philippe, he attached himself to the legitimist party, and appears on one occasion to have been seriously compromised, with several of the leading men of that party, in exposing the cause of the Bourbon claimant to the throne of France. He died on the 3rd of March, 1841.

The position occupied by Marshal Victor among the generals of Napoleon is not a very high one. Though his services to the Imperial cause were numerous and many of his exploits were brilliant, he is rather distinguished as a brave soldier than as a skilful commander. At the head of a division he executed with boldness and precision the movements indicated to him by his chief, but he was devoid of the military genius requisite to originate a skilful plan of battle. Hence, in a separate command, as in many instances in the Peninsular War, he was generally unsuccessful. He does not appear, however, to have had any remarkable remark concerning him by Napoleon, which O'Meara records: 'Victrix est une bête sans talons et sans tête.' ('Napoleon in Exile,' vol. i, p. 511.) Such a judgment probably speaks rather of the limits under which Victor's conduct, on his return from Elba, had excited. It is indeed scarcely possible that it was the real estimate he had formed of this general's military character, since he had raised him from the position of a private soldier to the highest dignities of his empire, dignities which were in every case the reward of some species of merit, and not the mere fancy of favouritism.

VIE, JOSEPH MARIE, one of the most celebrated French painters of the eighteenth century, was born at Marseilles on the 18th of July, 1716, and was the pupil of various of the great painters, among them A. Rivalz, of Toulouse, and finally C. Natoire, at Paris, whither he removed in 1740. He was very sickly in his youth, and his parents thought that even the fatigues of his studies were too much for him. He soon recovered from the attack of strength could not bear, and endeavoured to lead him to pursue other pursuits; his own enthusiastic devotion to art, however, got the better of all obstacles, and in the year 1743, he competed successfully at Paris, for the grand prize of the French Academy, and was appointed to the pension of the Académie Royale de Peinture et Sculpture. The subject of the picture was the Plague of the Israelites, in the time of David. In 1744 he departed for Rome and remained there until 1750, when he returned to Paris. Besides many works, which are now dispersed among private, he painted his six years' residence in Rome, including several church or altar-pieces of great merit, as the Slaughter of the Innocents, St John the Baptist of Montpelier, and the only two portraits by Vivien of the two sons of the cardinal of Armande. The portrait of Mme Germain and Saint Vincent receiving the Crown of Glory from the hands of an Angel, and the Sleeping Hermits. These were followed by a long series of works at Paris, many of which were dispersed among the public at the sale of his estate in 1770, indicating a decided revival in the French school of painting from the insipid puerile state to which it had been reduced by Vanloo and Boucher. The pictures of Viey approach the style and technical excellence of the scholars of Correggio, though for some time his works were much maligned by the scholars of Boucher and Vanloo, and among them his own mosty Natoire. His St Denis preaching to the Gauls, one of his best works, was sold to a superior to the picture by F. Doyen of the Muses des Arlons, illustrating the tradition of the picture made by St Genevieve when ferreting out her pen of confessions from the cup of which she was caressed by lightning in the year 1219. Viey's picture was placed in the church of St Roch, where Doyen's is also now placed; they are nearly the same size, being about 24 feet high. St Paul at Tarsus is another important work: in the French revolution, Viey was justified by his contemporaries, who gave him the title of regenerator of painting in France: Count Caylus had always been an admirer of his pictures. Viey died in 1785, and was buried in the church of St Eustache, and of nature as represented in the works of the best Italian masters, and he succeeded to a considerable extent in both respects; but his admiration for the antique was carried to the utmost extreme by his pupil Vatea and David and their scholars.

Viey was elected a member of the French Academy in 1754, when he gave as his presentation piece a picture of Dido laying Attic wings. In 1775, after the painting of his picture of St. Denis, which was exhibited in the Louvre in the previous year, he was decorated with the order of St. Michel, and was appointed director of the French Academy at Rome, where he resided from that time until 1781, and was elected in the meanwhile member of the Academy of St. Luke. After his return to Paris he became one of the rectors and director of the Academy there (he had previously been professor); and he was finally appointed principal painter to the king in 1789. This post he of course lost at the revolution, but he was from its foundation a member of the Institute of France; he was also created by Napoleon a member of the Academy of Science, a title which he accepted, and proved useful. He died at Paris, March 27, 1809, having nearly completed his ninety-third year, and he was buried in the Pantheon. He painted until within a year of his death. According to his will, his works were to be divided among the heirs of two hundred; this number would not be great, if many of them were not of very large proportions. Few of them have however been engraved; the St. Denis, already mentioned, which is by some considered his master-piece, has been engraved only in outline by C. Normand for the 'Annales du Musée,' published by Landon, and in the 'Musée de Peinture,' etc. of Revuel and Duchesne. His works are from various subjects, but chiefly from the Sacred Scriptures, from ancient and modern history, and from Greek mythology. Among his more celebrated pictures are—Julius Caesar contemplated by the seat of Alexander at Cezar and regretting that he was still unknown at an Age when Alexander was already crowned with Glory; the Consecration of the Equestrian Statue of Louis XV; Marcus Aurelius causing Provisions to be distributed among the Poor; St. Louis presenting the Regency of the Kingdom in his Queen, Blanche of Navarre; St. Jerome; the Embarkation of St. Martha; Christ breaking Bread; the Resurrection of Lazarus; the Virgin attended by the Archangels by Night; the young pupil of various of the great painters, among them A. Rivalz, of Toulouse, and finally C. Natoire, at Paris, whither he removed in 1740. He was very sickly in his youth, and his parents thought that even the fatigues of his studies were too much for him. He soon recovered from the attack of strength could not bear, and endeavoured to lead him to pursue other pursuits; his own enthusiastic devotion to art, however, got the better of all

sioned to the council of the army; he has thus been enabled to give a minute detail of several events, of which we might otherwise have remained ignorant. His history has rendered the more valuable from the fact, that it is probably the oldest historical record in prose which the French language possesses. The first edition of it was published at Venice in 1612. There, in 1542; the most valuable is that by the learned Du Cange, whose notes, says Mils, 'are as valuable as his notes on the Alcaid.' [Britannica Historians, P. C.] The title of this edition of Du Cange, which is relatively to be the most trustworthy, is as follows: Histoire de l'Empire de Constantinople, divisions en deux parties, &c., érite par Geoffroy De Ville-Hardouin, avec la suite de cette Histoire jusqu'en 1640, tirée du manuscrit de Philippe Emmanuel de Gons]. Le tout est contenu dans 'Charles du Frene, Sieur du Cange; Paris, de l'imprimerie Royale, 1657, in fol.' In this edition the old text is accompanied with a modern French version. The history of Ville-Hardouin is also to be found in vol. xxviii. of the Recueil des Historiens des Gaules et de la France; Paris, 1822, in fol. The text in this edition has been revised on three manuscripts, and is to be printed with a glossary.

VINCENT DE PAUL, SAINT, was born on the 24th April, 1581, at Ranquines in the parish of Puy, near the Pyrenees, in the present department of the Landes. He was the third son of Louis de Paul, a small land-proprietor, and cultivator of a small farm in that parish. The narrow means of his family promised him a life of laborious toil, and till the age of twelve he assisted his parents in the care of their farm. He had however from early youth manifested so great an acuteness of intellect and sensibility of disposition, that they were induced to endeavour to give him a suitable education. He was placed as a student in a convent of the Cordeliers at Agen, the residence of the bishop of his diocese. At the age of sixteen, he was considered qualified to become tutor to the children of M. de Commet, an advocate of Agen, and the magistrate of his native village. This situation enabled him to study from the same time to relieve his parents from the expenses attendant on his education, and to prepare himself for the ministry of the church, to which he had now determined to devote himself. He assumed the tonsure on the 20th December, 1608, and the next year he went to Toulouse, in order to follow the course of theology of that university. But he was compelled, on account of the slender patrimony which was allowed him, to combine the duties of a teacher with those of a student. In the year 1609, after having received a previous order, he was made a priest by the Bishop of Perigueux; in the same year the order was made him of the parish of Tith, one of the most valuable in the diocese of Agen, which he chose in order to devote himself more entirely to the study of theology. In this study, notwithstanding the difficulties under which he laboured, he soon became eminent, and on the 12th October, 1604, obtained the degree of bachelor of arts, in philosophy and economics, and which precipitated his election to a benefice in the diocese of Agen.

In 1605, a legacy of fifteen hundred livres, which had been left him by a friend who had died at Marseille, compelled him to make a journey to that city. After taking possession of his legacy, he was returning by sea, when he was taken prisoner by some Tunisian corsairs, and was wounded in the conflict. He has left us a minute relation of his capture and imprisonment, in a letter written to his early patron, M. de Commet, on his return to France in 1607, of which there is a copious extract in the Biographie Universelle. During his captivity at Tunis and Algiers, he became the slave of three successive masters; the last of them, an Italian renegade, he converted to his former faith. After a delay of ten months, he was sufficiently fortunate to induce his master to forego the temporal advantages of a residence in a land where he had declared his principle of Christianity, and to escape with him to France, in which country they landed on 28th June, 1607. At Avignon, the penitent renegade was publicly redeemed to the privileges and consolations of the religious state. Shortly after his ordination as the vicar-general of the pope, Paul V., who had performed this ceremony, induced Vincent and his companion to accompany him to Rome. There he became acquainted with the ambassador of the Pope to the sultan, a nobleman who selected him as an important and confidential messenger to Henry IV. He arrived in Paris at the commencement of the year 1609, and obtained several interviews with the king. His time however he chiefly devoted to the service of the sick of l'Hôpital de la Charité, near which his father bought a house. The next year he devoted himself to the care of the poor sick, and the reputation of Vincent rose still higher in the estimation of those who had witnessed the patience and resignation which he displayed under the false accusation.

His residence in Paris was followed by a period of support of several influential personages, whose friendship and esteem his merit had conciliated. Among them was Marguerite la Valet, sister of Henry III., and the divorced queen of his successor, who appointed him her almoner, and Pierre de Berulle, afterwards cardinal, and founder of the congregation of the Oratorians. By the latter he was induced to accept the cure of the parish of Clechy in the neighborhood of Paris, where he discharged his duties with exemplary diligence. His short residence in that village was blessed with the happiest results; not only were the sick attended to, but also the poor were relieved, and the afflicted consoled, but family discord and dissent in religious matters were made by his pious influence to cease.

In 1613, he was obliged to abandon this peaceful scene of activity, and to take the road to Rome, as the son of Philip Emmanuel de Gondi, Count of Joigny, and general of the galleys of France. These pupils of Vincent were destined to occupy an important position in the history of their country; one of them became the well known Duc de Retz; another, the famous cardinal, who acted so conspicuously a part in the civil wars of the Fronde. [Retz, P. C.] In 1616, he accompanied the Countess de Joigny to her country residence at Soissons, where he officiated as the priest of the diocese of Amiens, where he commenced a series of missionary labours among the inhabitants, which were eminently successful. The memory of this mission he was in the habit every year, on the festival of the conversion of St. Paul, of celebrating with pious gratitude. The following year, he left the residence of the Count de Joigny to undertake the care of the parish of Châtillon, in Brasso, where his labours were attended with similar success. It was there that he became established and organized a religious association for the relief of the temporal and spiritual wants of the sick and poor, to which he gave the name of the 'confrérie de charité,' which became established in so many similar institutions in France and other countries. Towards the end of the same year, he was induced to return to the Count's family, and, with the permission and co-operation of the Countess, a lady of pious sentiments, no less zealous of the religious and moral welfare of those under his spiritual direction, he undertook several successful missions in the dioceses of Beauvais, Soissons, and Sens. An opportunity was now afforded to him to labour in a cause still more dear to his heart, which pressed on him with a more urgent danger, disappointment, and difficulty. He was in the habit of accompanying to Marseille the Count de Joigny, whose situation as commander of the royal galleys rendered it necessary for him frequently to visit that city. He was there moved with compassion on witnessing the sufferings and severities to which were subjected the unhappy criminals condemned to the galleys. To ameliorate their condition and to alleviate their sufferings, he entered the pious task which Vincent took upon himself. He found them in narrow and unhealthy dungeons, almost entirely deprived of air and light, with bread and water for their food, disfigured by filth, and covered with wounds, these wretched victims of their own misdeeds, and of the misguided policy of the state, sunk shortly after their admission into a brutal state of ignorance and ferocity. Vincent began by examining every individual among them as their friend and benefactor, and, undeterred by the rude scoffs and jests to which he was at first exposed, and undismayed by the harangues of a pestilential disease, which was at that time raging in the prison, he pursued his charitable mission: his kindly manner, his patient attention to their wants, his reproofs, tempered by mildness and Christian charity, and, above all, his own example of humility and submission, had a great effect on their minds. His labours were attended with so much success among them as to secure a ready acquiescence in his efforts for their welfare. In short time, the most unexpected
success attended the improvements which he introduced and the reformation which he effected. The ameliorated condition of these criminals was sensibly felt and gratefully acknowledged by his patron, who called the attention of the king, Louis XVI, to the success which had attended the humane measures for the reformation of criminals under his care and to the devoted nun by whom it had been produced, and the king, with appropriate consideration for the services he had rendered, appointed Vincent de Paul bishop of Beauvais, to which see he was translated, and communicated to him the direction of the first convent of the Order of the Visitation, which he had lately established. [SALES, DE FRANCIS, SAINT, P. C. S.]

In 1626, Vincent established the first house of the Daughters of Charity in the town of Macon, one for men and the other for women. He next visited the city of Bordeaux, for the purpose of inquiring into the condition of the criminals there confounded to the galleys. On leaving that city, he visited his friends and relations in his native village; having assembled together those who remained of his family, he informed them of his determination to die as he had lived, destitute of all worldly wealth; told them that money left by a priest to his family was đàod prospered, and thus weaned them from any expectation they might have formed of obtaining property at his death. This resolution however did not prevent him, on a subsequent occasion, from furnishing his children with funds required for the education of their own children. He was, as the first residence of the new company he had formed. For the better watching of his infant institution, he left the family of the Count de Joyeuse, and retired to that college. In 1627, he had no little influence with the Congregation of the Missions authorized by letters patent from the king, and in 1631, formally approved by a bull of the Pope Urban VIII. During this period he was actively employed in establishing retreats for the members of the society, and for persons destined to enter the orders of the church; a measure which greatly tended to the reformation of many existing abusés. In 1632, he yielded to the repeated requests of the Prior of St. Lazurface, Adrien Lebon, to accept his house and property for the purpose of furthering his projects for the instruction and relief of the poorer classes of the peasantry. Small as were the beginnings of this institution, he lived to see the orders of the Daughters of Charity, a religious society which has spread over a greater part of Europe. The institution however which has probably been most beneficent is that which he established in 1634; it was composed of a community of women, devoted to the care of the sick and especially devoted themselves to the attendance of the sick; a branch of this society, called 'Les Dames de la Croix,' was intended for the sole service of the Hôtel Dieu at Paris. To Vincent de Paul this city indeed has been peculiarly indebted for many valuable institutions, whose utility is recognised to this day. Among them may be mentioned the hospitals of 'La Pitié,' 'Bicêtre,' 'La Salpêtrière,' and 'Les Enfants Trouvés,' or Foundling Hospital. [PARIS, P. C. F. FOUNDLING HOPITAL, P. C. P. C.]

The origin of this last-mentioned institution exhibits a striking proof of the disinterested zeal of Vincent de Paul, devoted to the establishment of the Foundling Hospital in Paris. From the number of children, the fruits of licentious intercourse or the victims of their parents' poverty, were daily exposed in the streets and public places of that city, and often left to perish. The pitiable condition of these innocent sufferers excited the compassion and stimulated the charitable zeal of this devoted minister of the church. For the purpose of affording them food and succour he visited the hospitals, and laid before the king's hospital, over whom his simple piety had already exercised a beneficial influence. He called them together at the commencement of the year 1640, and so energetically set before them the motive of their creation, the necessity of their existence, the importance of the cause of these unhappyfoundlings, that they determined to subscribe for the trial of taking under their protection all who should hereafter be discovered. The generous gift of an annual rent of 12,000 livres from the Queen of Austria was the first assistance they received in their humane design. Soon however the wants of these foundlings exceeded the funds which charity could raise; discouraged in their efforts, and fearful that the task which they had undertaken was beyond their powers, and abjured the cause. The Daughters of Charity were about to abandon their charitable enterprise. To avert so unhappy an issue to his charitable project, in 1648, Vincent called together greater and more numerous assemblage. He summoned to his aid the rich and the humble, urged in support of his cause, and pleaded the interests of these innocent outcasts of society in a language of fervid imagination eloquent, an eloquence unaided by the arts of a polished education, but which, nevertheless, conveyed deep-seated sincerity and ardent zeal. The termination of his address on that occasion has been recorded by a high authority as one of the finest efforts of the language. [Maur, 'Essai sur l'Eloquence de la Charité.'] [MAUR, P. C. S.] Rich and plentiful were the fruits of his energetic pleading; alms were collected in abundance, two large buildings were converted into hospitals for foundlings, and the capital of France was no longer disgraced by the daily exhibition in its streets of helpless children dying from the want of food and succour. Besides the hospital already mentioned, Vincent founded two others, which have been productive of considerable benefit: one at Paris, which went under the designation of the name of Jesus, for the maintenance of forty poor men, whose age had incapacitated them for any useful occupation; the other at Saint-Benoît-sur-Loing, and furnished with the revenue of a small estate. Autumn, in Burgundy, for the relief of the poor and sick among the numerous pilgrims who are accustomed to visit the shrine of that martyr.

While occupied in the formation of societies and in the establishment of institutions of his fellow-creatures, he was no less zealous and persevering in attending to the immediate wants of the poor and destitute in the reach of his influence. He prevailed with the pontiffs during the latter period of the reign of Louis XIII., suffering under the threefold calamity of war, pestilence, and famine. To that province, by his charitable exertions, for several successive years, Vincent caused considerable quantities of money, which he collected in Paris, to be sent for the succour of its inhabitants. His biographers differ with respect to the amount, the highest stated being two million livres, and the lowest from five to six hundred thousand.

During the wars of the Fronde, the Queen-regent, Anne of Austria, instituted a council for the settlement of disputes on questions of theology, and appointed Vincent de Paul its president. In this capacity, he took a prominent part in the religious controversies of that period and warmly espoused the cause of the Jesuits against the followers of Jansenius. [JANSENISIUS, P. C. F.; PORT ROYAL, P. C. P.]

Through his influence, eighty people were confessed of the reformed Church, and to have employed against his adversaries only the legitimate weapons of argument and exposition. The four last years of his life were spent under the burden of infirmities, which compelled him to keep within the precincts of the convent of St. Lazarus, where nevertheless he continued efficiently to preside over the interests of the community he had established. His death, which occurred on the 27th September, 1660, was preceded by severe and protracted sufferings, which were borne with his accustomed patience and resignation. His remains were deposited in the church of St. Lazarus, in presence of the assembled clergy and the highest dignitaries of the capital, who for the honor of that of their spiritual father; but perhaps the tears of most genuine affection were shed on this tomb by the multitude of the poor and needy, who gratefully remembered that they had often been comforted by his kind regard, either in body or in charity.

The pugnacious of this eminent minister of the church has been written by two of its most distinguished prelates, Boisguille, Bishop of Decize, and the Cardinal Mauz, last of these has been greatly admired for the beauty of its style and the energy of its expressions; it may be seen in the majority of the French edition sub l'Eloquence de la Claire. [MAUR, P. C. S.] The canonization of Vincent de Paul was consecrated by a ceremony, known in the church of Rome by the name of Beatification, by Benedict XIII., on 14th August, 1729, and he was canonized as a saint on 16th June,
VINCENT, by Clement XII., who appointed 18th July as the day of this festival in the Roman calendar.

The name of St. Vincent de Paul stands deservedly high in the list of benefactors of mankind. His entire life was devoted to the advancement of the best interests of humanity; he labored unceasingly on the theme of his will to abolish suffering, poverty and crime, and his presence was always attended by consolation and relief to their victims. Men of all creeds and persuasions have rendered homage to his worth, and his name is inscribed on his own church, the misericords in which he sent abroad, the vast sums of money which he caused to be distributed to the poor and sick, his untiring activity in ministering to their wants, his disinterestedness and self-denial, his evangelical patience and religious resignation; above all, his genuine humility, which, while it shed lustre on those of his charitable deeds which are known, has caused a large proportion of them to be unknown and unwritten, save in the records of the book of life; these, it must be allowed by all, are the real miracles on which stands the fame of this apostolic man.

The following is a list of the writings he has left:—1. 'Regulæ secundum Constitutiones conventuum Congregationis Missionis,' Paris, 1668; 2. 'Lettre au Pape Alexandre VII., pour solliciter la Canonisation de François de Sales, procureur de la Congrégation de la Charité,' Paris, 1680; 3. 'Ceremonial pour l'Explication des Règles des Sœurs de la Charité,' Paris, 1826, in 8vo. The two most important biographies of St. Vincent de Paul are those written by the Mme. de Capetegue, Paris, 1827, in 8vo. ('Biographie Universelle,' tome xix., Paris, 1827: the article in this biography is written by Lelaurier, and is valuable from the research and impartiality which it displays; 'Vie de St. Vincent de Paul, Fondeur de la Congrégation of the Missions and of the Sisters of Charity, by Mme. Collet, Priest of the Mission,' Paris, 1848: this was written by a Catholic clergyman, Dublin, 1848; 'Les Pères des Martyrs, &c., from Allan Butler, tradition de Godescard, Versailles, 1819, tome vi.; 'Penny Magazine' for 1838, p. 4; Abelly, Evêque de Rodez, 'Vie de St. Vincent de Paul, Paris, 1839, 2 vols. 8vo., the most complete and valuable biography of St. Vincent.)

VINCULARIA. A species of fossil Zoonephyra is referred to this genus of Defracea by Portlock, from the carboniferous limestone of Ireland.

VIENNE, CHARLES, died June 5, 1756, at his house, Aldershott, Hampshire. When or where he was born has not been ascertained. He is known as the author of 'A General and Complete Abridgment of Law and Equity,' 24 vols. folio, 1741-1751, and as the founder of the Vinenian Professorship of Common Law in the University of Oxford. The 'Abridgment' is of two house and a half volumes, and is an Index, by a Gentleman of Lincoln's Inn. It appears to have occupied only ten years in printing, but Viner was probably occupied many years previously in preparing it. Blackstone says he was half a century about it. This stupendous work was reprinted in 24 vols. roy. 8vo., 1792-1794, and was followed by 6 supplemental volumes, roy. 8vo., 1799-1806, the compilers of which were James Edward Watson, Samuel Comyns, James Scegwicke, Henry Alexander John Wyatt, James Humphreys, Alexander Anstruther, and Michael Nolan.

Vins have resolved to devolve the bulk of his property, as his will states, 'to the benefit of posterity and the perpetual service of his country,' bequeathed by his will, dated December 29, 1755, about 12,000l. to the Chancellor, Master, and Scholars of the University of Oxford, to establish a Professorship, and to endow such Fellowships and Scholarships of Common Law in the university as the produce of his legacy might be thought capable of supporting. The Professor is to reside three months in the English language, and is not to take the degree of admission, and a course of lectures on the laws of England every year in full term. The course is to consist of at least twenty-four lectures, to be read in one and the same term, with at least three months between two terms. As relates to the reading of the lectures, Easter and Trinity Terms are reckoned as one Term. There are at present (1840) two Fellowships with 50l. a year each, and five Scholarships with 20l. a year each. Both Fellowships and Scholarships expire at the end of ten years after each election.

Blackstone was elected the first Vinenian Professor. He had commenced his lectures on English law in the year 1765, and in his two years before the close of his will, he had written the notes and commentary, as well as the preface, which are to be found in his translation of the Institutes of Gaius. It is remarkable that Blackstone's lectures gave Viner the hint for founding the Professorship. The succession of professors is as follows:—1765, William Blackstone, D.C.L.; 1790, Robert Richard, author of 'A Short Introduction to the Law of England,' 1 vol.; 1797, Richard Viner, D.C.L., author of 'A Short Introduction to the Law of England,' 3 vols. 12mo.; 1803, James Blackstone, D.C.L.; 1824, Philip Williams, B.C.L.; 1843, John Robert Kenyon, D.C.L. ('Chamber's Biographical Dictionary; Oxford University Calendar,' 1846.)

VIOLENT STRINGS. [GODFREY, P. C. S.] VISMIA (in honour of M. de Visme, a Lienon merchant), a genus of plants belonging to the natural order Hypericaceae. The calyx is five-parted, the petals 5, usually villous on the inside. The berry membranous, the styles 5, stigmas peltate. The stamens are numerous, disposed into 5 bundles, opposite the petals, alternating with 5 glands or scales. The authors are small, roundish, 2-celled, bursting lengthwise, the seeds with a double covering. The species are protected with a dusty, rarely with pellucid petals.

V. guianensis is a small tree with a stem about eight feet high, the leaves ovate, lanceolate acuminate, dilated at the base, many-celled, with follicular stipules. The stem is protected with a dusty, rarely with pellucid petals. The leafy yellow and corymbbose. The berry yellowish, ovate, soft, and somewhat 5-celled. A spot of the leaves is recommended in intermittent fever. This species is native of Guiana and Brazil. There are about twenty other species growing in the East Indies, Bengal, and Guiana: those from Guiana yield a resins gum, which is used in European medicine. This species is native of Guiana and Brazil. There are about twenty other species growing in the East Indies, Bengal, and Guiana: those from Guiana yield a resins gum, which is used in European medicine.

VITRIOL Description of the Vitriolus Britannicus. [GAUDY, JAMES, P. C. S.] VITTORINO DA FELTRE, born in 1379, at Feltre in North Italy, studied at Padua under the celebrated Guarino of Verona, and afterwards became professor of rhetoric and philosophy in the same university. Being some time after invited by G. F. Gonzaga, lord of Mantua, to superintend the education of his children, Vittrorino repaired to Mantua, where a separate and commodious residence was prepared for himself and his family. Vittrorino was a man of strong mind, of distinction repaired thither in succession to avail themselves of Vittrorino's instruction, and among them Federico di Monte-feltro, afterwards duke of Urbino, Giberto, prince of Correggio, Taddeo Bentivoglio, afterwards lord of Forano, Gino, Battista Pallavicino, afterwards bishop of Reggio, Lodovico Torrino and Bernardo Brenzoni, who became afterwards celebrated as jurists, Theodore Gazz and George of Treviso, Ambrogio Traversari, and Camaldulenses, who visited the school of Vittrorino at Mantua, gives his Epistles (lib. viii. viii.) an interesting account of his system of education; and Carlo Romini, who died latter, has written a work on the same subject, entitled 'Ideae et praecedentem et vice, a disciplina di Vittrorino da Feltre a de' suoi discepoli.'

It appears from the example of Vittrorino, of Guarino Veroncone, and others, that education, in the larger sense of the term, was better understood in Italy in the fourteenth century than it has been since, but it was confined to the upper classes. Gymnastics formed part of a Vittrorino's system. He lived with his pupils and took his meals with them. Their fare was wholesome, but plain. He had tablets of various colours to teach his younger pupils the rudiments of reading. His older pupils were instructed in rhetoric, mathematics, and ethics. He was not the first that taught to his pupils how to conduct themselves. He was not the first that watched the disposition and abilities of each pupil, in order to adapt him to that particular professional course for which he was best adapted. Temperate in his corrections, he allowed time and leisure for his pupils, and he never showed himself out of temper. He was beloved by his disciples, and he loved them like a father. Such was the character of this distinguished preceptor.

VOLPI, GIAN ANTONIO, born at Padua in 1686, studied in his native town, and became a good Latin and Greek scholar. In 1717 he and his brother Gaetano Volpi established a printing-press in their house for the purpose of bringing out correct editions of classic authors, and they engaged for their assistant the printer Giuseppe Comino. This press—known by the name of Volpi-Cominiana, produced among others a valuable edition of Catullus with copious notes. The edition was much commended by scholars, and the city of Verona struck a gold medal, which was presented to Volpi; the title is, ' Catullus Veronensis et in eum Jo. Antonii Volpii novus Commentarius,' 4to., Padua, 1737. Volpi afterwards edited Tibullus and Propertius. He translated from the Greek into Italian the dialogue of Zacharias Scholasticus; he wrote a dissertation on the satire of the Boeotians: ' Liber de satyrarum Latinae natura et ratione, item paraphrasis perpetuas et commentarium uberrimum in X satyram Juvenalii,' Padua, 1744; he edited the poems of Sannazaro, with a biography of the author; he published a new edition of Dante; and he wrote three books of Latin poems, to which he added those of his ancestor and namesake Gian Antonio Volpi, the elder, who was bishop of Como and was one of the Fathers of the Council of Trent. Volpi was for many years professor of philosophy and of rhetoric in the University of Padua. In his old age he became blind, and he died in 1759. His brother Gaetano Volpi edited Sallust in 1722, and he was an active assistant to his brother at the press. He wrote an account of their joint labours: ' La Libreria dei Volpi o la Stamperia Cominiana.' Giuseppe Comino having died in 1752, his son Angelo Comino continued to carry on the business. Another brother of Volpi, named Giuseppe, undertook the continuation of Cardinal Corrini's great work, ' Vetus Latinum profitum,' which he completed.

(Tiraboschi, Storia della Letteratura Italiana, with the continuation by Lombardi.)

VOLTZIA, a genus of fossil (coniferous?) plants which occurs in the Magnesian limestone of England, and in the new red sandstone of Germany. (Bromniart.)

VOYAGE. [Ships, P. C.; Bottomy, P. C.]
WACE, ROBERT, MASTER. The name of this early Anglo-Norman poet is variously written in different manuscripts of his poems, and in the ancient writings which make mention of him. The most usual forms are Wace, Gasse, Gacos, Guisse, Hauce, and Huistace, names which appear to be abbreviations of Wacostche or Huistace. His Christian name is likewise doubtful, as he never styles himself otherwise than 'Master Wace.' Du Cange supposed it to have been Matthew, and Huet is the first writer who calls him Robert. He was born in the island of Jersey about the year 1112, and received his early education at Caen; he completed his studies, which appear to have been chiefly connected with the clerical profession, during a residence of some time in the territories of the King of France, and he afterwards returned to Caen, where Henry I. usually held his court. In this town he spent the greatest portion of his life; his chief occupation was the composition of metrical romances, so called from their being written in the Roman or vulgar dialect. The 'Roman du Rou', which he completed in 1160, was dedicated to Henry II., and was presented to him by Wace in person, who was rewarded with a canonry in the cathedral church of Bayeux; this poem immediately excited the attention of the French, and the public through the agency of the poet Michael of Henry II. He complains, however, and that somewhat bitterly, that the reward he received from the Duches of Normandy neither answered his anticipations nor came up to the promises they had made him. He is said to have died in England, about the year 1184.

The principal details in this brief notice of the life of Wace, are given to us by himself in his 'Roman du Rou.'

The rhymed chronicle from which this extract is taken is entitled 'Le Roman du Rou (Rollo) et des Ducs de Normandie,' and is the best known of the writings of Wace; it is held in high esteem as a monument of the language and as an historical document, which, though incorrect in some of its details and sometimes inexact in its dates, presents a faithful picture of society during that period. It contains the history of the Duches of Normandy from the first invasion by Rollo down to the eighth year of King Henry I., and not simply, as Haucler states, the narrative of the battle of Hastings and conquest of England by the Normans. In the first, or introductory part, written in lines of eight syllables, and presents us with the history of the first irruption of the Normans into England and France. The second part or section is written in Alexandreine, and relates the principal events which took place in the reign of Rollo; the third, in the same metre, the history of William Longsword and his son Richard, the first Duke of Normandy of that name; in the fourth part, which is the longest, he traces the three predecessors, he remarks the eight-syllable measure, and presents us with a sequel of the history of Richard, and that of his successors to the year 1106. [NORMANDY, P. C.] The whole poem contains exactly 18000 verses. He generally follows Duoden and William of Juinangles as his guides in the relation of his particular facts, but he adds many interesting and curious details which he reports as having received from his literary friends.

His description of the battle of Hastings [WILLIAM I., P. C.] is given with considerable minuteness of detail, and has been largely drawn upon by succeeding historians. Amongst the most noted is the English labourer, Wace says that they could not fight on horseback, nor shelter themselves under a buckler with one hand, while with the other they directed their blows against the enemy.

The other recognised poems of Wace are—1. 'Le Brut d'Angleterre,' a work which preceded his 'Roman du Rou.'

The date of it is ascertained by the following lines near the end of the poem:

* Pois ke Des 7 interration
Poir poce name reditation
M.C.L. et cing ans. (1123)
Plut mettre Wace en roman.

The principal incidents in it are derived from a Latin translation, by Geoffrey of Monmouth, of a poem composed in the dialect of Lower Brittany. The subject of it is a certain Brunus, who is imagined to have been the great grandson of Roesa, and who ruled over Great Britain. It contains nearly eighteen hundred lines, in the same metre as those above quoted, and is by some supposed to have been the first work containing the origin of Arthur's round table, his knights, and tournaments. [ARTHUR, P. C.]

The next authentic work of Wace is styled 'La Chronique sequence des Ducs de Normandie.' It commences with Henry II. and goes back to Rollo. It is a short poem of only three hundred and fourteen Alexandrine verses, and is published in the first volume of the 'Memoires de la Societe des Antiquaires de la Normandie,' p. 144. It must have been written later than 1173, as it makes mention of the troubles excited in Normandy during that year by the revolt of the sons of Henry II. against their father.

The other recognised poems of Wace possess less interest, and are not so generally known. The first of them is entitled 'L'Establishissement de la Feste de la Conception, dicte la Feste en Normandie; the second, 'La Vie de S. Nicolas,' of which Huet has published several extracts in his 'Theaurus Litterature Septentrionalis.'

The above-mentioned works are the only ones which have been preserved, and on their authenticity no doubt exists, the two other poems have been ascribed to Wace, 'Le Roman du Chevalier au Lion,' and 'Le Roman d'Alexandrie;' but, though they are undoubtedly productions of the twelfth century, they are now generally supposed by the best critics not to belong to Wace's hand.

The manuscripts of his poems are very numerous; there are complete manuscripts of the 'Roman du Rou' both at the Royal Library of Paris, No. 7367, and at the library of the Arsenal; in both of these Royal Library is supposed to have been written in the fourteenth century. The most ancient is in the British Museum, and was probably written in the first years of the thirteenth century; it contains however only the fourth part of the 'Roman du Rou.'

There is a valuable essay on the manuscripts of the 'Roman du Rou' by M. de Brequigny, in the fifth volume of his 'Notices des MSS. de la Bibliothèque Royale.'

In 1827, there was published at Rouen a remarkably fine edition of the 'Roman du Rou,' in two octavo volumes, with very valuable notes, by M. Frederic Pluquet, who had devoted several years to the laborious task of carefully collating the text of the various manuscripts in existence.

The following works may be consulted for a more ample account of the life and writings of Wace:—1. Capefigue, 'Essai sur les Historiens Maritimes des Normands dans les Gales,' 1823; 2. Depping, 'Histoire des Expeditions Maritimes des Normands, 1826; 3. Wheaton, 'History of the Normans,' London, 1831. In these two works there are copious selections from the 'Roman du Rou;' Depping particularly has very Justly appreciated the value of Wace as a poet and historian. 4. Pluquet, 'Notice sur la Vie et les Ecrits de Robert Wace, suivie de Citations extraites de ses Ouvrages,' Rouen, 1824. In this work will be
WAL 701

found the most complete account of the writings of Wasce. In the 'Guernsey and Jersey Magazine,' London, 1836, vol. ii., p. 89, is to be found a notice of Wasce, which is however chiefly a translation of Plutarch's Life of Varro, which was published from the Roman text by a very interesting analysis of the 'Roman du Rou.' Roquefort, 'Glosarrie de la Langue Romane,' Paris, 1808, 2 vols., will be found useful to the reader.

WAGA'TZ is a large island in the Russian government of Archangel, situated in the Frozen Ocean at the entrance of the Gulf of Kara. It is separated by the Straits of Waigats from the coast, and is about 70 miles long from the head of Nova Zembla. It lies between 57° 30' and 59° 25' E. long. and 67° 20' and 68° 6' N. lat. It is desolate, rocky, without wood, and almost without vegetation; it absolutely barren of all grass, hay, fish, and is inhabited by a few families of Samoelots, and frequented by the Russians for the sports of hunting and fishing. Some old accounts speak of mountains connected with the Ural, and a map indicates a mountainous chain, which corresponds with that on the continent. There are some other islands, Mal'digef, Dolgoi, and Blinof in the Straits of Waigats, which are small, desolate, rocky, low, without wood, and only frequented by the Samoelots and Russian fur-hunters. The strait was discovered by the Dutch in 1594, who were endeavouring to find a new way to China. (Isselbl, Handbuch; Stein, Lecom.)

WALKING WHEEL is a cylinder which is put in motion about an axle by the weight of men or animals; it is used for the purpose of raising water, grinding corn, and for various other objects. It is probable that a wheel so put in motion was employed in the East, in a very early age, to raise water; for Moscs reminds the posterity of Israel (Denteneronomy xi. 10), that in that country they saw 'water brought out and 'gaz' as a garden of herbs; and in China walking wheels are used for raising water to the higher grounds on which rice is grown. In a treatise on machines, which was published at Eisleben in 1661, there is a description of a walking wheel which was used for grinding corn; it consisted of an inclined plane of a circular form, and turned upon an axle placed obliquely to the horizon, the axle resting at its lower extremity in a gudgeon firmly fixed to the ground; and at its upper extremity, one which was attached to a part of the building in which the machinery was contained. The wheel or plane was made to revolve on its axis by men, who, while stepping on its upper surface, pressed with their heels against horizontal rail and with their feet along slugs of wood which were nailed to the surface in the direction of the radii; and, below the wheel was a pinion whose leaves, acting against the cogs of a trundle on a horizontal shaft, gave a revolving motion to the machinery.

A similar kind of walking wheel was at one time proposed in this country, but it does not appear to have been much used: it was provided with a brake which was made of a heavy and rendered immovable at the will of the person employed to give it motion; and consequently the danger of accidents from a failure of the machinery might be considered as obviated. Such a wheel could be used by a man who might place it on the ground, and put his power in equilibrum with different degrees of resistance; thus, when the resistance is great, he may walk near the circumference of the wheel, and when small, he may find a place near the centre at which he will act with most convenience to himself; but a serious objection to it is, that the force arising from the weight of a man being oblique to the surface of the plane, its effect in giving motion, compared with that of an equal weight applied at the circumference of a vertical wheel of equal diameter, is only as the sine of the inclination of the plane to the horizon (about 30 degrees) to unity; therefore the former effect is only about half of the latter. The weight of the man or men employed to walk on a large wheel of this kind causes its plane to bend; and when, in order to prevent this effect, the wheel is supported by vertical props, the friction is greatly increased, notwithstanding the application of friction rollers at the points of support.

Wheels for drawing water from deep wells, as well as for other purposes, were at one time constructed in the form of two or more hollow cylinders, which were hollowed out of a tree, the hollows being connected with passages, through which the water issued. The wheels were used by the women of menaries or animals moving on their concave surfaces; they were of considerable dimensions, sometimes about 15 feet in diameter, and had an advantage over the inclined plane in being less liable to get out of order. The weight of the moving agent, a horse or a man, could not, however, be made to act on the circumference at a point more than 20 or 30 degrees from a vertical line passing through the axle, or where a tangent to the circumference makes an angle of 25 or 30 degrees with the horizon, and consequently the effect of the moving power compared with that of an equal weight applied at the extremity of a horizontal diameter, is only as the sine of that inclination is to unity. Two ranks of men were sometimes made to walk in the wheel behind one another; when, since the rear-rank men were necessarily at a less distance than those in the front rank from a vertical plane passing through the axle, their weight might have been still more disadvantageously applied. The lives of the men employed to give motion to such wheels were evidently in great danger on any accident happening to the machinery.

In the year 1803 the late Mr. David Harkness, then in the service of the East India Company, obtained a patent for a wheel which turned on a horizontal axle by men on its convex surface; the wheel was six feet in diameter, and projecting about 3 feet 6 inches from its surface. It was constructed of boards or steps whose planes, if produced, would pass through the axle. On these boards the men trode as in the act of ascending steps, keeping themselves in vertical position very nearly at the extremity of a horizontal diameter of the wheel; consequently in the most advantageous circumstances for the application of their weight. Above the wheel were fixed a number of vertical bars, by holding which the men

(WAL) 701. A genus of Lycocoid fossil plants from the coal and oolite formations. (Sternberg.)
might keep themselves steady; a number of bars were also made to project horizontally from a fixed beam above the wheel, at about three feet from the board on which the foot of the man was placed in stepping; and taking hold of two of these, pulling upwards as if he were lifting two bodies from the ground, a man might add his muscular energy to his dead weight, so as to on emergency to press vertically with a force amounting to double that weight. The circumference of the wheel is about 19 feet; and in normal use, by means of a rope and weight of 1,930,000 pounds raised one foot vertically, or about 365 pounds raised one mile. According to the experiments of Coulomb, the daily action of a man ascending stairs unaided is equivalent to 201 pounds raised one mile vertically. [Animal Strength, P.C.S.]

The Tread-Wheel which has been introduced by Mr. Cabot into prisons as a means of employing the culprits in useful labour is of the same nature as that which has just been described [Transportation, P.C., p. 150]. These wheels, which are about 5 feet in diameter, vary in length from 8 to above 20 feet, and they are connected with machinery for grinding hemp, or hemp.
In 1754, he was appointed to the command of the squadron destined to co-operate with the expedition of Colonel Clive [Clive, Robert, Lord, P. C.] in the East Indies; and soon after his arrival in that country he received his Majesty's commission appointing him a captain of the red. His first exploit was the reduction of Fort Geriah, which was held by a piratical prince, who had for many years annoyed the English trade in the East Indies. The service was performed by Admiral Watson on the 12th of February, 1757. In this engagement he and his brother, with the wives and children of this prince, who had become his prisoner, was marked by the most courteous humanity. In the attack made by the French ships of the line to assist the Bengal, in conjunction with Admiral Pocock, he commanded the small fleet of only three ships of the line destined to cooperate with the French. The French had prepared to resist him by sinking several large vessels in the river below the fort; but the admiral having found a safe passage by carefully sounding as he approached, directed so severe a fire upon the enemy's defences, that, seconded by Colonel Clive's batteries on the shore, the place capitulated in less than three hours (24th of March, 1757). By the capture of this fort, a large number of prisoners, one hundred and eighty-three pieces of cannon, and a considerable booty fell into the hands of the English. With this exploit may be said to end this admiral's short but successful career; on the 16th of August 1757, he fell a victim to that unhospitable climate. His death was received with the utmost regret at the court and private; but his amiable character, his military abilities, and his high merits, are his best epitaph. His brother, a well-known poet, was admired for his skill and bravery, and beloved for his moral qualities and amiable disposition. On the 18th of June, 1763, the memory of his services was consecrated by the erection of a monument in Westminster. The inscription is as follows: 'To the memory of Charles Watson, Vice-admiral of the White, Commander-in-chief of his Majesty's naval force in the East-Indies, who died at Calcutta the 16th of August 1757, in the 44th year of his age. The East India Company, as a grateful testimony of the advantages which they obtained by his valour and prudent conduct, caused this monument to be erected.'

(Waterman's Historical Repository, for the years 1758 and 1763; Lives of Illustrious Seamen, etc., London, 1803; Smollett, Continuation of Hume's History of England.)

Wavre is a town in the Province of South Brabant, in the kingdom of Belgium, situated on the river Dyle, in the 30th degree of longitude, and 50th degree of latitude. It has about 4500 inhabitants, who cultivate tobacco, have a considerable trade in corn and cattle, and several breweries.

Wavre has become celebrated by the battles of the 18th and 19th of June, 1815, between the Prussians and the French under General Grouchy. After the loss of the battle of Ligny, Büchter had taken (on the 17th) an advantageous position with the rest of the 3rd corps. The French, however, were not prepared to wait for the 10th corps coming from Lière, partly to effect more easily his junction with Wellington, who had engaged to maintain as long as possible the position at Mont St. Jean, while Büchter hastened to support him with the 3rd corps of the Russian army. The whole army, except the 3rd corps, was already on the march, when Marshal Grouchy with a far superior force suddenly appeared and attacked the town of Wavre.

General Thielmann immediately turned to meet him, but the other corps continued their march. A severe action between Thielmann and Grouchy was interrupted by the night, and renewed the following morning; when both parties, having learnt the result of the battle of Waterloo, retreated.

(Hassel, Handbuch; Stein, Geographical Lexicon.)

WAX-MODELLING. Wax has been in all ages an important agent in the art of statuary; and in the formative art generally, whether as a fine art, or for the purposes of science. In statuary it is used in making the models for the metal cast, but more formerly than at present, for now clay is frequently substituted in its place: it is however still used by silversmiths in casting cups and other cylindrical or spherical objects, especially such as are required to be kept from the markings of joints, to avoid injury to the design or embossed work. In fine art it is used in forming imaginary objects, and in the decoration of basi-reliefs; and it is also very usefully and largely applied in the preparation of anatomical models, especially in pathology, and in the preparation of fruit, flowers, and many objects of the natural history. A good article of wax is described, as a fine art, is frequently termed the ceroplastical art (ceroplastica, from ἐγκαταστάσεις, and ἀρτος, the art of fashioning into forms).
WAX

Wax was formerly indispensable in metal-casting, though when and how it was first used is wholly unknown. It may have been used for the models of solid casts in the earliest periods. Wax was generally used in hollow casting, which was a later invention, and which will presently be described; though of an art so entirely practical, no description can convey more than a general idea of it.

Different writers of different ages give various directions for the preparation of the wax to be used. Vasari, who doubtless mentions that used in his own time, recommends the admixture of a little tallow, turpentine, and pitch, with the commonest vegetable wax. This was then coloured with a little red ochre in powder, which must be mixed with the wax in its liquid state. It may be made any other colour in the same way. A French mixture is—to one hundred pounds of yellow wax, ten pounds of turpentine, ten pounds of pitch, and ten of hog's-lard, which probably would be similar in its properties to the mixture described by Vasari. When the wax is melted, great care must be taken that it does not boil, or it cannot be required when cold. M. Fiquet, in his 'Art du Mouler et Plâtre,' of which there is an abstract in Panckoucke's 'Encyclopédie Méthodique,' gives the following compound for founder's wax—to four of wax, mix one of tallow, one of tallow, and one of Burgundy pitch, which when melted together are fluid and manageable. This was probably the composition used by J. B. Keller and Girardon in preparing the mould for Girardon's equestrian statue of Louis XIV., which was cast entire, or in the 'Sartiello.' Several other mixtures are and were probably employed by different sculptors; the above however were those employed in France and Italy in the great ages of founding, when the wax method was generally in use. Wax may now proceed to describe the methods of its application.

Andrea Verrocchio, a celebrated sculptor of the fifteenth century [VERROCCHIO, P. C.], is said by Vasari to have been one of the first among the moderns to introduce casting from moulds taken from life, or, in Vasari's words, to bring the practice into general use—'che fu de' primi che conociassa e metteva in uso' (ed. 1668). These casts he made in wax and in plaster; and some writers have spoken of him as the inventor of moulding from the human figure, and others even as the inventor of casting in plaster; neither of which is said nor could have been intended to be conveyed by Vasari. Many arts have been known, and occasionally practiced, before they have been applied to the ordinary uses to which they were well adapted. There is in Florence still preserved in the cathedral a cast thus formed from the head of Brunelleschi, which being examined and remarked, must have been taken with Verrocchio was only fourteen years of age. And with regard to casting in plaster, if metal casts were made long before the time of Verrocchio, it is more probable that plaster casts were also made. The first distinguished Italian founder of modern times was Andrea Pisano [PIANO, P. C. S., p. 426], who modelled the gates of the Baptistery of St. John at Florence, which were cast by some Venetian founders. In 1332. The same sculptor had previously sent by Giotto a present of a bronze crucifix to Pope Clement V. (1305-1314) at Avignon, which must have been about 120 years before Verrocchio was born. This crucifix is represented as having been of excellent workmanship; it must have been fashioned consequently by an artist or artists well acquainted both with mould-making and with casting, and the idea therefore that either art can have been ever practiced at so late a period as Verrocchio is quite untenable. The fact of bringing artists from Venice to cast the gates of the Baptistery of St. John does not so much show that Florence was without good metal-founders, as it shows that Verrocchio had obtained sufficient for his own works of this class. William Austen, a celebrated English founder, was anterior to Verrocchio. [AUSTEN, WILLIAM, P. C. S.] Bell-casting, which was practised throughout the middle ages, is not so well understood as iron casting, the latter art in its process is of quite a different character from the modeling of works of imitative art. However, at whatever period and by whatever process the early Italians first prepared their moulds, it is evident that they must have obtained in all works the consequence used wax in the preparation of the model for the casting. The ancients and Romans also most probably used wax for the same purposes. There are few ancient illustrations of this art; the most notable of these is the equestrian statue of Marcus Aurelius before the Capitol at Rome. This monument is hollow, and cast in two parts; and probably the ancients method was not very different from that described by Verrocchio. The weight of the model and mould was on the following plan:—When the model of the statue was finished, a safe mould of plaster and brick dust was made from it, in many parts. [MODELLING, P. C. S.] Each of these parts, being marked and numbered, and removed from the model, was then oiled, and carefully filled on the inner side to a certain thickness, an inch or two, with the modelling-wax already described; the thickness depending upon the height or position of the parts, the larger parts being the thickest, for the metal is destined to fill exactly the space occupied by the wax. When all the parts of the mould were thus prepared, the whole was again put together, the plates being supported by wooden strakes to support it firmly in each direction; the lowest parts of the mould being first placed, and the joints of the wax of the various contiguous parts being filled in, and the pieces carefully united as the cement was softened. When this process had proceeded. When the whole was put together, it was bound on the exterior with strong bars of iron attached to the extremities of the bars of the interior framework. The mould is made in a hollow shell, with thick casting of wax all over the proof body termed in English a core (in some books written corps), by the French noyau, by the Germans Kern, and by Vasari the anima. Air-vents must be made in the shell before the casting of the core.

When the core is fixed, the original mould or shell is taken off, and a wax model of the statue appears to the eye. The sculptor now examines his wax model, and improves it where there is occasion and repairs or makes good all imperfections. When it is perfectly finished, the preparation for the founding commences. Over this wax statue a new fire-proof mould is made of plaster, brick dust or sand, cow-hair, and horse-dung, vigorously packed and fixed tightly by the proper number of iron bars, set at first as a fine liquid plaster, is put on in many coats with a brush, and care must be taken that every particle of wax is well covered. When the shape was formed by the covering before the successive coat is put on, and the composition may be gradually made of a coarser mixture. When this new shell or mould is of a sufficient thickness and is properly strengthened with iron bars, it is fixed and kept in position, and then to weigh what you get out of the mould afterwards and to see that they nearly tally. If any wax is left in, there is danger of the mould bursting, independent of the hard unchangeable inederelauing and inedifice for the metal. The quantity of metal is required to be melted accurately ascertained. The great difficulty and long process of melting out the wax was the cause of what is called the wax method of casting first heard of in the bronze statues of the ancients. The quantity of wax to be melted out, the quantity of metal required to be melted accurately ascertained. The great difficulty and long process of melting out the wax was the cause of what is called the wax method of casting first heard of in the bronze statues of the ancients. The quantity of metal required to be melted accurately ascertained.
no longer considered desirable to cast a monument in a single quoin. [Bronsor, P. C.]

When the wax is at length melted out, the mould must be strengthened by brickwork, and the whole pit must be closely filled with coals to prevent the heat from escaping. When the mould is thus filled with metal; the original iron framework, which was constructed before the casting of the core, keeps both the core and the mould in their proper places; and six vents in various parts of the mould permit the escape of the air from the metal. When all is ready, the furnace is opened at a given signal, the liquid fire runs in the channels simultaneously into the mould, and that part of the work which was previously soft wax becomes permanent bronze. The cast is accomplished when the metal pours out from the vents. When cool, the mould is broken away piecemeal, and the metal is exposed. The core is then removed from the inside through an aperture made on purpose; the whole is then repaired and finished by the bronze-workers. [Bronsor, P. C.]

Johann Balthasar Keller, who cast in this method the statue of Louis XIV., was a Swiss, and originally a goldsmith. He was born at Zurich, in 1638, and died at a wax foundry, called the Royal Foundry, in 1720. There is a print of the statue by C. Simon: it was cast in 1699.

It is quite a misnomer by Croiset [L’Art du Moulage, etc.,] that only half a century after the execution of this monument no one could be found who was capable of casting a monument of Louis XIV. for Bordeaux; and the process of casting a core is spoken of by the Mémoires de G. Faubourg, in which it is described as a process practised for four or five centuries, the statue of Louis XIV. in 1699, the practice of the Italian sculptors in and before Vaas’s time was for not so ingeniously as the method just described. The core was not cast, but built up and gaged on an iron frame, and layer by layer in modellling, until it was within the intended thickness of the metal, that is to say, as the core was burnt dry before the successive layer was put on. The composition of this core or anima was the same as that of the mould—a mixture of cow-hair, horse-dung, brick-dust, and plaster. The parts of the mould taken from the original model were now well oiled and each separately filled with wax: these pieces of wax, when hard, were taken out of the pieces of mould and built up against the core, and fitted by judgment and measurement. When the whole wax model was thus built and cemented together with wax, and pins when necessary, the mould for the metal cast, as in the other process, was gradually covered over it, and, when of a proper thickness for the model, each layer was then burnt out, and the cast accomplished as in the other case described. In some casts the metal is made to enter at the bottom of the mould so that in its own weight it will find its way to the top of the figure; when they arrive at the forum, they are scared upon chairs of ivory; and then exhibit the noblest object that can be offered to a youthful mind warmed with the love of virtue and of public glory. For who would not with like concern and delight behold so many illustrious men thus living, as it were, and breathing together in his presence? Or what spectacle can be conceived more grand and striking? The person also that is appointed to baragwine, when he has exhausted all the praises of the deceased, turns his discourse to the rest, whose images are before him; and, beginning with the most antient of them, recants the fortunes and the exploits of every one in turn. By this method, which renewed continually the remembrance of men celebrated for their virtues, the fame of every great and noble action becomes immortal; and the glory of those by whose services their country has been benefited is renouned, and delivered down to future times. (Hampton’s translation.)

This wax-modelling has continued apparently from the time of the Romans until the present day. In the middle ages it was used for the making of wax images. The first modem however of this class noticed in the history of art is Orsino, the contemporary of Andrea del Verrocchio, in the middle of the fifteenth century. Vaas represents the works of Orsino as a wax-model, and says that they were comed to demonstrate the manners and customs of the people, and that he attained, through the advice of Verrocchio, the highest excellence in his art. Verrocchio and Orsino made some interesting figures together, of which three are described by Vaas as something remarkable. The conspiracy of the Pazzi in 1478 was the cause of the production of these figures: they were voted by his friends in commemo-

ration of his escape. Orsino made, under the direction of Verrocchio, three wax images of Lorenzo of the size of life. The frameworks or skeletons of these figures were made of wood and cane, and the heads, hands, and feet were cast in wax, of considerable thickness, but hollow; they were then furnished with hair and glass eyes, and painted in oil-colours to the exact imitation of life; and were draped in clothes which had been worn by Lorenzo; to give the draperies a fixed character. All the figures were altogether life size, and very successful, says Vasari, that they appeared to be living. One of them was placed in the church of the Monaste di Chiarito, in the Via di San Gallo; another in the Ser- viti Church of the Madonna dell' Orazione; and the third in the church of Santa Maria degli Angeli at Assisi. In this Ser- viti church were many other wax figures by Orsino, of all which were marked with an O, in which was an R, and above it a cross; but they have all long since perished. Vasari adds that few works of later wax-modellers were to be compared with those of Orsino, and complains that the art had declined. A few years however after the death of Vasari, Jacopo Vio vivi distinguished himself by a model on slate, in coloured wax, of Michelangelo's Last Judgment in the Six- tine Chapel. It was engraved by Ambrosio Brambilla, and a particular description of it was published in Rome in 1599. — "Discorsi sopra la mirabile opera di Busso-RiUijevo di cer- stuessa con colori, scolpiti in pietra nera, da Jacopo Viovi."

Two centuries after Verrocchio, and one after Vasari, this art was developed in Paris, and was used with the utmost success by Cataneo and Giulio Zunno, born at Syracuse in 1655, to the preparation of anatomical models and pathological examples. Zunno obtained a European celebrity for his two groups of figures representing the different stages of corruption of the human body, and the effects of the plague. He modelled also an anatomical head at Paris, which is described in the Mémories of the French Academy of Sciences, of 1701, the year of his death. (Zunno.)

The first collection of anatomical preparations which was made for the purposes of science is that of the Institute of Bologna, established by Benedict XIV. It was commenced under the direction of Eccelo Betti, and the preparations were made by Giovanni Manzolini of Bolog- na and his wife Anna Morandi Manzolini. Manzolini died at Bologna in 1755, aged 59. There are some of his models in London and in many other cities of Europe. Anna Manzolini obtained still greater celebrity than her husband; she executed all or the greater part of the obstetric models in the Stanza Osteria of the Institute which were prepared under the direction of Dr. Antonio Galli. She also gave public lectures on anatomy in Bologna, illustrating her discourse by appropriate models. She died in 1774, aged 57. (Crespri, Felina Pitrice, where there are portraits of both the Man- zolini.)

There is a still more extensive and remarkable collection of wax anatomical models in the Museum of Natural History at Florence; it was established by the Grand-Duke Leopoldo, and is kept in chambers in which casts are exhibited by various artists, but the principal contributors to its treasures were Felice Fontana and Clemente Susini. The works of the earlier modellers in wax are set apart in a chamber by themselves; here are some of the models of Zunno, among which is one showing the whole anatomy of the human head, similar probably to the one made at Paris.

The Museo Dupuytren at Paris is celebrated for its morbid specimens; it is perhaps the richest pathological collection in the world. It was purchased by the University of Paris, of the heirs of M. Dupuytren, the celebrated anatomist. Most of the works of it have been adopted by the University, and good wax-modellers are numerous. The Museum of University College, London, contains many excellent specimens by the late Mr. William Vau.

These wax models are made in various ways, but the purest wax is used, which is the case also in all works where the wax is the final substance of the work. Different modellers use different compositions; and some allowance must be made for hot and cold wax; what would be suitable for a large model would not be suitable for a small one, and vice versa. The weather might be too brittle for winter use. Some modellers use simply wax and a small proportion of Venetian turpen- tine; others wax, resin, common turpentine, and a little olive- oil. Others use a mixture of 8 parts of wax, 2 of resin, and two thirds of turpentine.

It is seldom if ever used pure, as in all objects to be modelled white or some colour must predominate: for instance in modelling the brain, white in powder must be mixed in the composition, and the same respect must be had with regard to the predominant colour of every object to be modelled.

No strict rules can be given for the process of modelling, as each modeller will soon acquire methods of his own, and generally speaking, stick to them. But we may state his peculiar processes, imagining it to be detrimental to their interests. However, we may speak of general principles. Nearly all wax models are cast from moulds, and the casts only made in a few cases. Some, however, cast in one, others cast in two, and sometimes even in three. The moulds are generally taken from the objects themselves, either in plaster of Paris or in a composition of bees'-wax, Burgundy pitch, and Venice turpentine, with a very small quantity of olive-oil. The two first are nearly of the same consistency; even when cold, if properly mixed, which must be learnt by experience, the mould is elastic or flexible; and if made thin, when cut on the edges can be peeled off the casts in pieces with- out any danger to the cast; in making moulds in plaster of Paris, the object moulded must sometimes be destroyed to render the mould available. Round objects must be moulded in two or more parts. Sometimes when the object is cast in the mould, the mould must be destroyed before the cast can be removed, and in destroying the mould there is danger of de-stroying the cast also; the elastic mould therefore has great advantages in such cases over the plaster mould. When only one view of an object is presented, and it is only slightly convex, the plaster mould is quite sufficient, except the object itself, as the brain, presents a very uneven and delicate sur- face, the mould must be moist with water, but not absolutely wet, or the water would injure the very delicate surface, which occurs in some pathological cases: the mould may be moist- ened by pouring water on it, and keeping it in a dish of water, when it will soon absorb sufficient moisture for the purpose. The mould must not be oiled when any delicate work is to be done, as the oil will dissolve the surface of the wax, and thus destroy the principal aim of the cast. The wax-composition mould must be slightly touched with a soft hair-tool with oil, to enable it to peel away afterwards without the slightest danger to the cast: but to make it harder and more rapid, a small quantity of oil it retains is immaterial.

When the cast and made, and what they call back up (that is, strengthened with a corner composition within), the process of painting commences; but all effects cannot be given by mere colour, some morbid deposits and effects required to be expressed by adding wax of the proper colour with a hair-pencil or other tool. The colouring is done from the natural object repre- sented, with fine hair-pencils and powder colours moistened with turpentine and tempered with a little wax; simple water is also sometimes used as the colouring vehicle. When the colouring is finished, the whole is covered with mastic varnish. In cases where the morbid effects or evidences of disease are of a distinct substance from the healthy texture, different col-oured wax should be used in casting the healthy and diseased portions, and the parts may be corrected by modelling. The same principle is applied in the preparation of anatomical models of natural history, as in preparing anatomical models: but fruit, which is generally in full or high relief, will require piece-moulds, that is, to be moulded in several pieces, which is done half or part at a time. Flowers are not all cast at once; they are prepared from leaves of coloured wax made expressly for the purpose. These leaves are cut the required shape; they then, with the necessary colour and a hair-pen, receive their local tints; and are finally joined and fashioned into the re- quired flower. Insects are modelled by combining the two processes. In moulding objects with hair or delicate raised ornament, the cast is very carefully prepared, and the collection is then made, unless they are wet. Dry firm objects may be moulded without oil; the plaster must be removed as soon as it is set.

It remains yet to speak of the mode of making images. These are made in various ways, but the purest wax is used, which is the case also in all works where the wax is the final substance of the work. Different modellers use different compositions; and some allowance must be made for hot and cold wax; what would be suitable for a large model would not be suitable for a small one, and vice versa. The weather might be too brittle for winter use. Some modellers use simply wax and a small proportion of Venetian turpen- tine; others wax, resin, common turpentine, and a little olive- oil. Others use a mixture of 8 parts of wax, 2 of resin, and two thirds of turpentine.

It is seldom if ever used pure, as in all objects to be modelled white or some colour must predominate: for instance in modelling the brain, white in powder must be mixed in the composition, and the same respect must be had with regard to the predominant colour of every object to be modelled.
the checks, lips, and eyebrows; the whole then may be covered with wax, which must be poured over it two or three times, until the surface is well covered; it regularly may be secured by re-heating and melting of the wax and asbestos; it runs in usual means of a hot iron or burner (called cautery by the antients) which must be held near it until the whole has a uniform brown color. The paper or the block will show through with the wax, and the head will require but the hair, the eyes, and a few local touches to finish it. Masks may be also dipped in wax, or the wax may be put on with a hair-tickling brush to the mask or keps; or a wax-fig and may be backed up or strengthened with strong paper pulp. There are however other methods of modelling wax figures, but no method can be properly explained by a verbal description. With a few pieces of the celestial sphere it may be reconstructed and it deserves to be remarked that in this work we find the first notice of the method of determining geographical longitudes by the angular distance of the moon from some star; he recommends, for this purpose, a new instrument which has long since been disused by mariners. In 1522 he published at Nürnberg, in 4to., his 'Opera Mathematica,' in which is contained a tract on conics; he also published a work on Trigonometry, in five books, containing a great number of astronomical and geographical problems.

Werner wrote explanations of the construction and use of meteorological instruments; and it is said that he collected a number of observations with a view of discovering from them rules for determining the changes which take place in the atmosphere. He executed a machine in which the movements, s. a., were made to resemble formally to the Ptolemaic system; and he wrote a work on The Movement of the Eighth Sphere. He died in the year 1529.

WESTERN PORT. [WALES, NEW SOUTH, P. C.] WETHERELLIA, a genus of fossil fruits from Sheppy. (Bowerbank.)

WHITSTONE, GEORGE, a voluminous writer of prose and verse, lived in the latter half of the sixteenth century. Both the place and time of his birth are unknown; but he is claimed kindred with Sargent Plantagenet of the family which held property in London. His history was that of a succession of misadventures. He began by wasting his patrimony in seeking a place at court: he then served abroad as a soldier, and was an eye-witness to the fall of Sir Philip Sidney at Zutphen; he next returned to the abortive expedition of Gilbert to Newfoundland; and, finally, returning to England, he appears to have been chiefly occupied in the course of the rest of his life in literary labours, of which he had previously practiced occasionally, and now attempted with indifferent success as a means of subsistence. He is now chiefly known as having been the author of the two plays of 'Curse upon Eggs and Cobweb,' which, having been printed in 1578, ranks as one of our earliest extant comedies; though it has the further interest of having the same plot with Shakspere's 'Measure for Measure.' It is said to have been written between 1577 and 1579. In Chalmers's English Poets, Whetstone's Life of George Gascoigne: of his other works, a curious account, with specimens, will be found in Mr. Coller's 'Poetical Decameron.'

WHITE, REV. JOSEPH BLANCO, was descended paternally from an Irish Roman Catholic family. In the early part of the last century, William White came over to Seville, in Spain, where he succeeded to the then flourishing business of an exporting merchant carried on by his mother's brother. He was raised by the king of Spain to the rank of the nobleman, his posterity retained. But after his death the business fell into the hands of his son, the house failed, and the family were left for a time with very limited resources. This son had married a Spanish lady of the name of Crespo y Nere, connected with the old Andalusian nobility; and Joseph Blanco White, commonly designated in Spain Don Jose Maria Blanco y Crespo, who was born at Seville, 11th July, 1775, was their son.

The commercial business of the family had been re-established after the bankruptcy, and Joseph was placed in the first instance in his father's counting-house. When he was about twelve years old, however, his parents complied with his own desire of allowing him to be educated for the church. In the year 1800, he was a student in the college of Seville in the profession to which he had thus chosen soon took possession of him. He came to England in March, 1810, and spent the remainder of his life in this country. The same year he set up in London a monthly periodical work in Spanish, entitled
William Frederick I, King of the Netherlands, Grand-Duke of Luxembourg, Prince of Orange Nassau, was born at the Hague on the 24th of August, 1772. His father, William V, King of Orange-Great Britain, was descended from John the younger brother of the great William I. of Orange, and died at Brunswick, April, 1806. His grandfather William IV., the first Hereditary Stadtholder of the United Netherlands (from 1748 who died in 1751), had re-united the possessions of the four branches of the line of Nassau—Orth, Hadamar, Siegen, Dillenburg, and Diem, with his own branch, that of Diem. His mother was Frederica Sophia Wilhelmina, daughter of Prince Augustus William of Prussia. In 1778 he made a journey to Germany, and passed some time at the court of his uncle Frederick William I., who died in 1785, for a marriage.

After his marriage on the 1st of October, 1791, to Frederica Louisa Wilhelmina, daughter of Frederick William of Prussia, he, in conjunction with his brother Frederick, succeeded to the title of Grand-Duke of Luxembourg, and as such was invested with considerable and extensive powers in the Dutch army; but many impediments were occasioned by internal dissensions, the patriots, who had been put down in 1787 by a Prussian force, secretly intriguing against Hesse-Cassel. Governor-Prince of Orange, who had taken refuge in France, and on the 1st of February, 1798, the National Convention declared war against the Stadtholder. Hoping with the assistance of the patriots, to obtain possession of the rich provinces of Hesse-Darmstadt, composed Dutch Brabant, which was however recovered by the hereditary prince, who was commander-in-chief of the Dutch army, which was joined by a body of the allies, after the victory of Neerwinden on the 18th of March, which had been gained over Duhmusschu by the Austrian army under Coburg. The hereditary prince then hindered the French army of the North from penetrating into West Flanders; but on the 18th of September he was attacked in his position between Menin and Dunkirk by the Austrians, and was driven back with the most gallant resistance, in which his brother Prince Frederick, who commanded the right wing, was wounded, he was obliged to retreat behind the Scheldt. Soon after this the hereditary prince received the devolution, and then, the provisions of the Austrian army, drove the enemy beyond the Sambre; but in the great battle of the 16th of June, 1794, the French having taken Charleroi by storm and defeated the prince's left wing at Mons, he was again obliged, by the directions of Prince Coburg, to retreat. The Austrians retreated, before the French and Jourdan, behind the Meuse; and the hereditary prince, with his weakened army, had no alternative but to cover the republic and to connect the army of the Duke of York, and to the south he fell, and the frost enabled the enemy to pass the Waal on the ice, so that Pichegru entered Utrecht on the 17th of January, 1795. The party of the patriots favored the enemy, and the stadtholder was unable to save the republic, forsaken by its allies. His sons had resigned their commands on the 18th of January, and William V., with his family and court, left the country for a few days; but on the 19th of January he returned to Utrecht. On the 20th of January he surrendered the Dutch and Spanish Journal, 'Las Variedades,' which was published quarterly, and continued for about three years. Other separate works followed, both in Spanish and English; those among the latter that attracted most attention being his 'Practical and Internal Evidence against Catholicism,' 1826, and again 1826; 'The Poor Man's Preservative against Popery,' 1825, several times reprinted; 'Second Travels of an Irish Gentleman in search of a Religion,' (in answer to Moore's well known work) 2 vols. 12mo., Dublin, 1833. He was also an occasional contributor to the 'Quarterly Review,' to the 'London Review,' established in 1829 (of which he was the editor for the first 18 numbers), to the 'Dublin University Review,' and to the 'Journal of Education' (in an early number of which he wrote one article on the State of Education in Spain), to the 'Dublin University Review,' and to the 'Quarterly Review.' He resided occasionally at Oxford and Dublin as well as in London; and in 1850 he settled in Liverpool, where he continued till his death, which took place on the 30th of May, 1851. He left a son, who, in 1840, was a major in the English army. Of W. G.'s writings probably those that will last the longest are the papers which have been published since his death under the title of 'The Life of the Reverend Joseph Blanco White, written by himself,' with posthumous additions, edited by John Hamilton Thom, 3 vols. 8vo., London, 1845.
and others, were exerting themselves at Amsterdam, the Hague, Rotterdam, Zwolle, and other places, to effect the resurrection of the house of Orange. William was at that time in the Netherlands; the mutiny had been occasioned by the revocation of the Edict of Nantes, for the support of the Netherlands. When the victories at Leipzig approached the frontiers of Holland, the inhabitants of Amsterdam rose on the 16th and 17th of November, and one of the first measures of the insurgents was to proclaim William as king. This prompt resolution of the Dutch patriots to seize the opportunity of recovering their independence was attended with the most important consequences. The prestige of the nation, which had been so often defiled, was re-established; but France still had great resources; the formidable barrier of the Rhine was not yet passed, and when that decisive step should have been taken it might be followed by an immediate war in which France would never venture to think of crossing the Rhine before the return of spring. What might have been the consequence if the allies had waited till the spring, instead of carrying the war into the winter? It is true that, before the end of December, the insurgents in Holland might have brought about such a change in the situation of the Allies as would have deprived the French of a field of action during the winter; but so much time to Napoleon, may be inferred from what actually happened in the wonderful campaign on the banks of the Seine and the Marne in 1814, in which Bonaparte displayed all his extraordinary resources as a military genius.

As soon as William learnt what had passed, he embarked on the 29th of November, and landed at Scheveningen on the 29th. He was received with acclamations by the people of the Netherlands, and was immediately recognized as Amsterdam, where Kemper and Scholten, the commissioners of the provisional government, had issued on the 1st of December a proclamation, announcing 1 Holland is free,' and 'William I, the sovereign Prince of this free country.' The prince gratefully assented, and declared that a constitution must guarantee the rights and liberties of the people, and secure them against all encroachments. Twenty-three fortresses were still in the hands of the French, who were encamped near Utrecht, but the army of the allies, and the volunteers, who were called to arms, occupied the country. William hastened the armament of the people, and appointed a commission to negotiate a truce. The treaty was signed on the 29th of March, 1814, by the deputies of the people, and then sworn to by the prince. He had already taken possession of his hereditary dominions in Germany, before the end of August, and the prince of Orange, the kings of Belgium and Liege, together with the Seven United Provinces, should be formed into one kingdom, and on the 16th of March, 1815, the treaty was concluded at the Hague. The union of the Netherlands and Duke of Luxembourg. But he was obliged to cede to Prussia his hereditary possessions in Germany for Luxembourg, which after the 22nd of May, 1816, belonged to the German Confederation, and which he now raised in May to the rank of a grand-duchy.

The union of so many provinces, the inhabitants of which, though of the same origin, differed very much in manners, customs, and institutions, made it necessary to do something to make the new constitution necessary. A commission, consisting of an equal number of Dutch and Belgians, was appointed to make such changes as were requisite. After the king had approved of this commission, it consisted of the British government and deputies from the southern provinces, and finally proclaimed on the 26th of August. In 1814 the king founded the military order of William, and in 1815, after the battle of Waterloo, a Belgian Legion, called the Junta. On the 30th of June, 1816, joined the Holy Alliance. He resided alternately at Brussels and the Hague. On the 17th of May, 1816, a Dutch fleet, under Admiral Van der Capellen, joined the British fleet, and compelled the day to conclude a treaty, by one article of which all Christian slaves were to be restored to liberty.

In the interior of the kingdom, a want of harmony between the inhabitants manifested itself on several occasions, which, but for the moderation and firmness of the king, might even then have led to serious dissensions: the unbounded influence of the Roman Catholic clergy, even over the higher classes in Belgium; the mutual jealousies and conflicts of the different provinces; the dissatisfaction of the latter with the long residence of the court at Brussels; divisions in the northern provinces between the friends of the old republican system and those of the new or monarchy, and lastly the necessity of providing against the danger that was kept within bounds only by confidence in the character of the king, and the mild conciliatory principles of his government. In the foreign relations the government, in the main, succeeded; the British government, the Grand-Duchess Anna of Russia improved the connexion with that empire, but especially weakened the interest taken by England in the affairs of the Netherlands. Some differences had arisen with Prussia, with which kingdom a closer union was however caused by the marriage of Prince Frederick to the Princess Louisa, daughter of the King of Prussia, on the 21st of May, 1825.

The union with Holland and various commercial treaties with foreign powers had given an extraordinary impulse to the manufactures and commerce of Belgium, especially of the cities of Antwerp and Ghent, but the government could not succeed in blending the Dutch and the Belgians into one nation. Their mutual aversion was manifested with great acrimony in the church, in the army, and even in the assemblies of the States general. The intolerance of the Roman Catholic clergy, encouraged by the Papal nuncio in the Netherlands and the Jansenist bishops of Utrecht, Haarlem, and Davenport, who had taken the oath of allegiance to the king, and the prohibition of the French language in all judicial proceedings, created great irritation in the southern provinces, and the conservative party was not satisfied, and was necessary to modify it in several points; and besides these important differences respecting religion and language, there were several financial points in which the interests of the northern and southern provinces clashed; and which, notwithstanding several very beneficial measures, could not hinder the final separation of the two parts of the kingdom. The union of Belgium and Holland had subsisted for fifteen years. The cities, the manufactures, and the commerce of Belgium, had attained the highest degree of prosperity, but nothing could conciliate the refractory spirit of the Belgians with the phlegmatic character of the Dutch, nothing could conquer the aversion of the people of Brabant and Liege, founded on differences in manners, religion, and language, from Protestant Holland. The July Revolution in France revived the old mutinous pride of the Belgian cities, and a rising of the mob in Brussels, on the 24th of July, 1830, commenced the revolution which separated the northern and the southern provinces. In consequence of a second insurrection in Brussels, on the 20th and 26th of September, the national party rose, and the conflicts arose between the government and the insurgents. King William, the armed insurgents, commanded by foreign officers, which ended in the retreat of the Dutch. Meantime the king, yielding to the desire of a Belgian deputation of the 18th of September, had been driven from Brussels, and on the 13th of September to discuss with them the question of a separate administration, and an alteration of the fundamental law. The two chambers were in favour of it, but the insurgents, supported from Paris by the Propagandists, contended for a total separation, which already existed in fact, when the five powers, Great Britain, France, Austria, Russia, and Prussia, imposed a cessation of arms on both nations, and, by the protocol of the 4th of November, 1830, recognized the independence of Belgium. This is not the place to inquire into the motives which induced four of the great powers, instead of executing these engagements, to conclude a treaty of peace and alliance, by which they, had they themselves erected as a security against the future encroachments of France, to unite with France in demolishing their own work. But justice requires us to acquit the king of this crime, and to interpret the occasion as was dictated by honour, good faith, and regard for the interest of all, and far from prejudicing the rights or legitimate interests of any government, it entitled him to the esteem and gratitude of all the cabinets of Europe.

King William protested, on the 12th of July, 1831, against the eighteenth articles presented by the great powers, particularly against the last, which would have excluded the Belgians from the alliance of the Netherlands, with extraordinary enthusiasm, resolved to have recourse to arms; not to obtain a re-union with Belgium, which it did not wish, but for the assertion of its rights. On the 2nd of August the Prince of Orange, at the head of 70,000
men, crossed the Belgian frontier; Turnhout and other places were taken; one Belgian army was defeated near Hasselt on the 17th; another again near Louvain on the 10th; but a French army advanced by forced marches, and the English and French ambassadors at the court of Brussels negotiated an armistice, according to which the Prince of Orange evacuated Brussels on the 14th, and laid down his arms before the war. A treaty in twenty-four articles was then proposed by the London Conference, which was acceded to by Belgium, but rejected by King William. Russia, Prussia, and Austria having also acceded at the same time to the armistice, and being able to undermine the said treaty, it was modified; but France and England had recourse to measures of coercion. England blockaded the coast of Holland, an embargo was laid on the Dutch ships, and the citadels of Antwerp were bombarded between December and January. This memorandum, with the French invasion, was a serious blow to the situation of the Dutch and Belgian army. It did not immediately lead to peace between Holland and Belgium, but a suspension of arms was effected on the 21st of May, 1832. The London Conference resumed its difficult task; many important questions remained to be settled: an interminable series of protocols ensued; William did his utmost to delay the conclusion of the peace negotiations; he knew of some turn in his favour, and hostilities between Holland and Belgium were on the eve of recommencing at the end of 1832, and were prevented only by the remonstrances of the Conference. At length,7 provoked chiefly by his financial embarrassments, William gave way, and, on the 4th of February, 1839, signed the twenty-seven articles, modified to his disadvantage; and the definitive treaty was concluded on the 19th of April, 1839, by the King of the Netherlands and the Belgian. 7.

But though Holland was now wholly separated from Belgium, there was great excitement in the Dutch Chambers in 1839. There were very active financial laws; numerous judicious reforms instead of which proposals were laid before them for a loan of fifty-six millions of florins. The loan was rejected on the 20th of December, and the budget on the 23rd; a loan of only six millions was granted, and the budget voted for six months only. At the next meeting of the States-General, in March, 1840, the king caused several modified projects of law to be laid before them; in consequence of which the civil list was fixed at one million and a half of florins; and it was resolved to vote the budget for two years only instead of ten as hitherto. But notwithstanding this endeavours of the government to satisfy the people, the discontent with the king and the ministers increased. The king's passion for the Countess Henriette d'Outremont, a Roman Catholic lady, excited the general indignation of the people, so that he declared on the 26th of March, 1840, that he renounced his projected union with her. This affair, and the discovery of an extensive conspiracy in Belgium, in which the Dutch appeared to be concerned, and finally the financial difficulties of the state, induced the king solemnly to resign the government on the 7th of May, 1840, into the hands of the States-General. Under the name of Count of Nassau, with an immense private fortune, he fixed his residence at Berlin, where, on the 17th of February, 1841, he married the Countess d'Outremont, and received the Duchy of Nassau and the title of Prince of Nassau property to his family, besides a gift of ten millions of florins to the Dutch treasury.

(Baron de Keverberg, Du Royaume des Pays Bas, vol. iii. 8vo. La Hague, 1844; Brockhaus' Conversations Lexicon, 1848; Mémoires tirés des papiers d'un homme d'état; Mr. Chalm, Narrative of the Revolution in Holland, London, 1814.)

WILLIAMS, DANIIEL, D.D., a Protestant Dissenting minister of the Presbyterian denomination, was born at Wrexham, in Denbighshire, in the year 1644. The disadvantages of his early education, and even of the nature of his mind, and by his own diligence. He was one of the first of the new generation who entered the Christian ministry after the ejection of the Nonconformists in 1662; and at the age of nineteen he was regularly admitted as a preacher. His first years in the ministry were passed in preaching in several parts of England, though the times were so unsettled that there was little prospect of his continuing his learned profession. This circumstance, however, did not deter him from remaining among the Nonconformists, though his talents and his prudence would have enabled him to enter the church-establishment with a fair chance of advancement; but, on these days, not even granted by the government in Ireland than in England, Mr. Williams repaired to the sister-country, and unexpectedly received an invitation to become chaplain to the Countess of Moth, which he accepted. Some time afterwards he was called to the Dissenting congregation in Wood Street, Dublin. Here he remained nearly twenty years, and filled his station with great credit, being at the same time much respected by the Irish Protestants in general. During his residence in Dublin, it was the desire of an Irish family, with a considerable fortune. Towards the close of the reign of James II., his warm opposition to Romanism exposed him to some danger; and he consequently came to England, where he was received with signal honour, and enabled to live in London, and to be provided with a copy of the King's use of an address upon the king's dispensing with the penal laws. Mr. Williams frequently took his stand with the opposition. He ' never would,' he said, 'concur in laying down the character of the king; his majesty's' support was the question prevalent in the conference of dissenting ministers. He now became the patron of those Irish Protestants who fled to England from the violence of Tyrconnel; assisting them himself, and procuring for them the sympathy and aid of the public. He rejoiced greatly in the Revolution of 1688; and was often consulted on Irish affairs by King William. In 1700 he went to Ireland on his own private business, and to visit his friends, by whom he was warmly received, and whose services in the cause of Protestantism were even acknowledged by some who had been prejudiced against him. About the middle of the year 1700, Mr. Williams purchased the house in Bishopsgate Street. Here he continued twenty-seven years. He was most esteemed by Mr. Richard Baxter, on whose death, in 1691, Mr. Williams was chosen to succeed him at the College of Seraphers. He had a large circle of controversy created parties among the Dissenters connected with this lecture, and Mr. Williams rendered himself obnoxious to those who advocated the tenets of Dr. Crisp, the acknowledged champion of certain Romish doctrines. A reception was prepared at the offices of the said party, and the author was sent for to Mr. Williams' lecture at Pinners' Hall, where he took place, and another Tuesday lecture was established at Salford Hall. On this occasion, Dr. Bates, Mr. Howe, and Mr. Alspoh, who had been among the lecturers at Pinners' Hall, retired with Mr. Williams. On the 1st of November, 1736, Mr. Williams' works were reprinted, Mr. Williams, by request, wrote his 'Gospel Truth Stated and Vindicated.' a work of which Mr. Alspoh, in his 'Faithful Rebeck,' says, 'It is fairly written, rationally argued, exactly methodized, and finely designed.' Mr. Stephen Hob having charged this work with Socinians, an appeal was made on both sides to Dr. Stillington, then Bishop of Worcester, and to Dr. Edwards of Oxford, both these learned persons being regarded as masters in that controversy; and they both acquiesced Mr. Williams of the charge. In his 'End of Discord,' wherein is demonstrated that no doctrinal controversy remains between the Presbyterian and Congregational Ministers fit to justify longer divisions, he distinctly states the opinion of the 'Orthodox, the Socinian, and the Antinomian' on the doctrine of the 'satisfaction of Christ,' and he adheres to the views of the first. So great was the value of this work that he added the name of son Williams. Under the name of Count of Nassau, with an immense private fortune, he fixed his residence at Berlin, where, on the 17th of February, 1841, he married the Countess d'Outremont, and received the Duchy of Nassau and the title of Prince of Nassau property to his family, besides a gift of ten millions of florins to the Dutch treasury.
proves that he was in advance of the age among his contemporaries.

Townshend, in the close of the reign of Queen Anne, Dr. William became apprehensive respecting the safety of the Protestant succession, from the measures of the prime minister, the Earl of Oxford; and he renounced on the subject his seat in the House of Commons, on which he had held it for many years. It happened, not long after, that a copy of a letter which Dr. Williams had written to his friends in Ireland on Lord Oxford's measures fell by accident into the hands of a lady who was a close companion of the second volume of his philosophical and religious works, who immediately took the letter to her lordship, who, already displeased with the doctrine for which he had volunteered, now never forgave him. On the accession of George I. in 1714, he left Townshend, and took lodgings on the ad- dress to his majesty, at the head of the London dissenting clergy of the three denominations; and from this time it has been usual for this body to go to court on similar occasions, it being one of the bodies who are received on the throne, and by their committees in the royal closet. Dr. Williams's health had by this time visibly declined for a year or two, though he still continued the exercise of his ministry. At length, after a short attack of asthma, he died on the 26th of January, 1716, in the seventy-third year of his age, and was buried in Bunhill Fields. In his funeral sermon, Dr. Evans, who had been his co-pastor for eleven years, eulogised him as 'a man of inven- tion, a poet, a philosopher, a faithful, a memory, and vigorous affections, which were cultivated by much application to study.' His moderation was shown by his desire for a com- prehensive church Union in which the dissenters should be included. He was acquainted with a large part of the dissenting clergy, and was always kind to such dissenters as would not be included. His great con- scientiousness and his unusual readiness to forgive injuries are also mentioned in his praise. He was accustomed to deliver a lecture to young people on Christmas-day, which was attended by vast audiences from all parts of the town. His discourses and treatises extend to six volumes 8vo, and have been collected and published at different periods: the last volume consists of Latin versions of several of his treatises, translated for the benefit of foreigners, agreeably to the instructions of his will. He also directed that his treatise entitled 'The Vanity of Childhood and Youth' should be rendered into Welsh for the use of schools, and printed often for the benefit of the poor.

Dr. Williams bequeathed the bulk of his estate to benevo- lent and useful objects. Having provided for his widow, he left donations to the Society for the Reformation of Manners; for the education of youth in Dublin; for an itinerant preacher to the native Irish; to the poor of the Wood Street congregation in Dublin, and of that in Hand Alley in London; to the French refugees; to the poor of Shoreditch parish; to assist poor ministers and students; to several ministers' widows; to St. Thomas's Hospital; to the London workhouse; to the Society for promoting Christian Knowledge in Scotland and Ireland; and for the maintenance of charity-schools in Wales. He sold his estates to the university of Glasgow, which at present furnishes six handsome exhibitions to students for the ministry among the poor, and he has not been omitted in his will by his trustees. The last grand bequest in his will was four thousand pounds to the establishment of a public library in London. For this purpose he had bought Dr. Bates's collection of books for between five hundred and eight thousand pounds, to add to his own. He directed his trustees to erect a suitable building, the site for which was purchased by them in 1727, in Red Cross Street; and the library was opened in 1729. All persons may obtain admission on application to one of the trustees. Since the library was established, very considerable additions have been made to it by legacies, as well as by contributions in money and books. It contains upwards of sixteen thousand volumes, and in 1841 a new catalogue was published. Among its most valuable possessions are tracts and sermons which had never been catalogued before.

Dr. Williams's library will be memorable in future time as the source of preparation for many of those noble struggles for civil and religious liberty. The whole of the three denominations continued on both sides to be great social parties, and that state, as it were, second volume of his philosophical and religious works, which were so frequently read by them, was supported by their united efforts brought about the repeal of the Corporation and Test Acts when differences arose, and the want of religious sympathy in the sections of the body began to show itself. In 1815, by the opposition of the Unitarian and Congregationalists, and the remaining orthodox Presbyterians, few in number, alone remained in the connection. The government considerably yielded to the sece- pending party the right of addressing the throne separately under the name of the Presbyterian denominations; and the Congregationalists, the Baptists, and the remaining orthodox Presbyterians are still known and recognised by the government as the 'Three Denominations,' whose meetings are now held in the Congregational Library, Bloomsfield Street.

(Dr. Williams's Works: Calamy's Continuation: Bogue and Bennett's History of Dissenters; Congregational Magazine for 1836.)

WILSON, DR. THOMAS, a noted statesman and scholar of Queen Elizabeth's time, was the son of Thomas Wilson of Stroby, in Lincolnshire. He was educated at Eton and at King's College, and was one of the two sons of the Duke of Suffolk. In 1551 he published 'The Rule of Reason, containing the Art of Logic;' and in 1553, 'The Art of Rhetoric.' Both works were frequently reprinted in the course of the century, and both have received much commendation from modern critics; the latter in parti- cular being held to give the author a title to be considered as the earliest critical writer in the English language. Full specimens of it are given by Watson. On the accession of Queen Mary, Wilson found it convenient to retire to the Continent. He took the degree of doctor of laws at Ferrara; but, on proceeding to Rome, was apprehended by the Inqui- rational and was brought to the scaffold under pretense of being charged with having written certain treasonable writings. On the death of Pope Paul IV. (1565), the discontented populace of Rome broke open the prison of the Inqui- rational; and is said to have been put to death after a period of charge being said to have been found in the works he had published. WILSON, ALEXANDER, was born at Paisley, in Scotland, July 6, 1766. His mother died when he was ten years of age, and his father, embarrassed with the charge of a young family, soon married. In 1779, Wilson was apprenticed to a weaver for three years, on the expiration of which he worked about four years as a journeyman weaver, and then abandoned the loom, and spent nearly three years as a pedlar. From an early age he had been cultivating a talent for poetry which he imagined himself to possess, and in his excursions for the sake of his wares endeavoured to procure subscriptions for a volume of his poems, but without success. The volume was never published, but verses and single poems were published in newspapers and separately. 'The Laurel disputed,' a poem on the respective merits of Ferguson and Ramsay, he recited before a literary society in Edinburgh, and published the poem in 1791. In 1792, he published a play on his 'Watty and Meg,' which some at first sacristed to be, to the small gratification of Wilson. His poetry however made no impression on his countrymen in general, and he resolved to emigrate to the United States of North America.

On the 14th of July, 1794, Alexander Wilson landed at Newcastle, in the State of Delaware, with a very small sum of money in his pocket, and was reduced to poverty. He was employed for a few weeks by a copper-plate printer; he then resumed successively his former occupations of weaver and pedlar, but after some years became well known as a poet, and ultimately turned printer, and pursued his new avocad- cation at different places in Pennsylvania and New Jersey.

At length, in 1802, he made a contract with the trustees of a
school at Gray’s Ferry, on the river Schuylkill, in the township of Kingsess, about four miles from Philadelphia, and here he became acquainted with Mr. Bartram, the botanist and naturalist, whose gardens were always open to him, and whose conversation delighted and improved the taste for natural history which his turn for observation and his rambling life had developed. Here too he became acquainted with Mr. Lawson, the engraver, who gave him instruction in drawing, providing him with landscapes and sketches of the American figure, but with little promise of his becoming a draftsman, till Mr. Bartram proposed a trial of birds, in which he succeeded beyond the expectation of his friends; and from that time his lifelong passion of his after-life was brought into play. Writing to a friend in Paisley, in June, 1828, he says: "Close application to the duties of my profession, which I have followed since Nov., 1796, has deeply injured my constitution; the more so, that my rambling disposition was the worst calculated of any one’s in this world for the austere regularity of a teacher’s life. I have had many pursuits since I left Scotland—mathematics, the German language, music, drawing, &c., and I am now about to make a collection of our finest birds." In October, 1804, Wilson, accompanied by two friends, set out on a pedestrian journey to the Falls of Niagara. They reached the Falls, and satisfied their curiosity, but were overtaken by the snows of winter on their return. One of his companions remained with his friends near the Cayuga lake, the other availed himself of a conveyance; but Wilson walked on with his gun and bundle, through trackless snows and uninhabited forests, over mountains and along dangerous rivers, and reached home at the beginning of December, after a journey of 1257 miles, of which he walked 47 the last day. All the time he could spare was now devoted to the examination of birds, and making drawings of them in colours. In 1806 Mr. Bradford, bookseller, of Philadelphia, being about to publish a new edition of Rees’s ‘Cyclopaedia,’ engaged Wilson as his Chief editor. Soon afterwards he explained to Bradford his views of a large work on American ornithology, and the bookseller undertook the publication.

Wilson was assiduous in attention to his duties as assistant editor, while at the same time he prosecuted the great undertaking which had become the favourite object of his ambition with an enthusiasm which was characteristic of him. At length, in Sept., 1808, the first volume of the ‘American Ornithology’ was published. From the date of the first arrangement a prospectus had been put in circulation, in which the nature and intended execution of the work were specified, but no adequate idea had been formed of the book which was in preparation, and when the superb volume made its appearance the American public were alike astonished and delighted. It was in folio, with plates carefully engraved from Wilson’s own drawings, coloured after nature, and with admirable letterpress descriptions; the price was 120 dollars. In the course of September, 1808, Wilson journeyed eastward and northward, and during the winter went through the southern States, exhibiting his book and endeavours to obtain subscribers. He visited in fact every town within 150 miles of the Atlantic coast, from the river St. Lawrence to St. Augustine. He received many promises, but few subscriptions. Wilson however was not depressed.

The second volume was published in 1810, and soon afterwards he set out for Pittsburgh on a journey to New Orleans. From Pittsburgh he descended the Ohio by himself in a skiff. He started on the 24th of February, and on the 17th of March moored his boat safely in Bear Grass Creek, at the rapids of the Ohio, after a voyage of 720 miles. His hands had suffered a good deal in rowing. He had made excursions from the banks of the river, as he proceeded, with his gun and drawing materials, in search of new species of birds, of which he made drawings and wrote descriptions of the spots which he shot. He afterwards walked from Louisville to Lexington, 73 miles, and on the 4th of May set out from Nashville for St. Louis through the wilderness on horseback, with a loaded pistol in each pocket, a loaded fowling-piece, belted across his shoulder, a pound of powder in his flask, five pounds of shot in his belt, and some biscuits and dried beef. On the fourteenth day he arrived at Natchez, in Mississippi, after a journey through swamps and across the prairies, which had nearly killed both his horse and himself. The other volumes of his work were brought out in succession, with astonishing rapidity and regularity; the number of his subscribers increased, and before his death included perhaps every royal personage in Europe. In 1812 he was elected a member of the American Philosophical Society. In 1813 he published the 7th volume. He had completed the pictorial materials for the 8th and 9th when he was carried off by an attack of dysentery in his forty-eighth year. He died August 28, 1813, at Philadelphia. The 8th and 9th volumes were completed and published in 1814 by Mr. George Ord, who had been his companion in many of his exploring expeditions. Mr. Ord supplied the letter-press descriptions for these two volumes, as well as a biography of Wilson in the 9th. Three supplemental volumes were afterwards supplied by Charles Lucian Bonaparte, folio, 1822—1828.

Wilson’s pictorial representations of the birds are considered to be of great excellence. His descriptions are not only technically accurate, but strongly clear and graphic in whatever relates to their motions and characteristic habits. It is a delightful book. The mind is so much absorbed with the images and scenes as to be hardly conscious of the act of reading.

Wilson was about five feet ten or eleven inches in height, handsome and vigorous, but rather slender. He was always distinguished by the neatness of his dress and appearance. He was a man of the strictest honesty and the most scrupulous regard for truth; social, affectionate, and benevolent, but somewhat irritable under contradiction and critical objection. He was never married.

(Memoir of Wilson, annexed to the American Ornithology, by Alexander Wilson and Charles Lucian Bonaparte, in Constable’s Miscellany.)

WOOD FISH [Anarellis, P. C. S.]
WOLF BANE [Acanthum, P. C. S.]
WOOD, DECOMPOSITION OF [Timber, Preservation of, P. C.]
WODSDIA, a genus of ferns, having circular sori, with an inferior indusium, divided at the edges into numerous capillary segments. W. libeia is one of the rarest of our British ferns; it is found in only two localities in England, in Wales, and one in Scotland. It takes root in the fissures of rocks and in the bleakest part of mountainous places. The fronds are elongated, the pinnae triangular, with deep lobes, the rhizoma tufted. There are many species of this species, which are by some writers considered as distinct species, but Mr. Babington thinks this division unnecessary. (Babington, Manual of British Botany; Newman, British Ferns.)

XANTHIAN MARBLES. These interesting marbles, which will shortly be opened to the public in the apartments built expressly for them on the western side of the British Museum, are the attention of the British collection of antiquities. They consist of a large collection of sepulchral marbles of various ages, which were first made known to the European public by Mr. (now Sir C.) Phillpotts, an authority on the subject. These marbles were the work of the Xanalytics, a small country on the southern coast of Asia Minor. [Avantolla, P. C. S.]

Xanthus is an ancient town, and was built on the river of the same name (now Echidn-Chali), at the distance of seventy stadia, or nine or ten miles, from its mouth. The first mention of the Xanthians in history is in the first book of Herodotus, c. 176, where he describes the capture and destruction of their city, in the middle of the sixth century a. c., by Harpagus, the general of Cyrus. Herodotus says that the Xanthians, after burning their wives and children, were all destroyed by the soldiers of Harpagus. He continues, that those who inhabited the city in its time were all foreigners except eighty families, who were absent on a foreign expedition. He says nothing of their monuments. Five centuries later nearly a similar fate happened to them when they were besieged by Brutus: the city was destroyed, and only one hundred and fifty Xanthians were left, says Plutarch, and this against them. Many of the monumental buildings of Xanthus must have perished in this second destruction: it was however again restored, as is evident from the Greek inscriptions and the state of its ruins when discovered by Sir C. Fellow. These different conceptions in some way account for the various characters of its monuments and inscriptions.

The origin of the Xanthian collection of marbles may be briefly described. In 1830 the attention of men of letters and artists, both in England and in other countries, was called to the subject by the following publication and its illustrations:—A Journal written during an Excursion in Asia Minor,' by Charles Fellows, 1838. In this account the remains of Xanthus were represented as of a very early age, and portions of its walls as Cyclopian. The ruins were in many places covered with inscriptions, many in a perfect state, but in an unknown language, which Mr. Fellows represented as resembling in appearance that of Phoenician or Etruscan. Many of the ruins, the rock tombs, were described as resembling those of Persepolis. The ruins consist of walls, temples, tombs, triumphal arches, and a theatre, and are situated in a site in a region of extreme distance, in 1832. Some crowned with rocks, others rising perpendicularly from the river, which is seen winding its way down from the woody uplands, at times becoming invisible between the mountains in which it rises. These picturesque ruins are covered with sculptures, and their elegant designs, says Mr. Fellows, evince the talent of the Greeks; and the highly poetical subjects of the bas-reliefs, some of them blending in one figure the forms of many, probably to describe its attributes, are also of Greek character.

The account of these ruins attracted more attention than their discoverer expected, and soon after the publication of his first journal, he made, in 1840, a second journey to Xanthus, to give a more satisfactory account of his discoveries. The results of this journey appeared in 'An Account of Discoveries in Xanthus, being a Journal kept during a second Excursion in Asia Minor,' by Charles Fellows.

In consequence of the more accurate and satisfactory account in this work, and the representations of various persons to the British Museum, a portion of the marbles, consisting of some of these Xanthian marbles and Xanthus and preserving them from further destruction, an expedition was fitted out in the autumn of 1841 for the purpose, and permission being obtained for the purpose. In the spring of 1842 the first expedition was deposited in the British Museum in 1842. In 1843 a second expedition was sent out, and the remainder of the Marbles arrived towards the end of the following year. The Marbles are large and many, and consist of many of the famous and the whole will be shortly opened to the public, partly arranged in the Museum as they were originally found by Sir C. Fellow. The tombs have been named, from their sculptures, the Winged-chariot Tomb, the Harpy Tomb, the Chimera Tomb, and others, according to their features. The figures were of the Xanthian collection. One, the Winged-chariot Tomb, was the work of a sculptor who had entirely produced the figures, the others in fragments. These two entire tombs, which were first made known to the European public by Mr. (now Sir C.) Phillpotts, an authority on the subject. The Xanthian collection. One, the Winged-chariot Tomb, is a remarkable one, and stood on the side of a hill. The marble being finely worked, the polish has greatly assisted in its preservation from the effect of the atmosphere. The roof is somewhat grey, and the fractures of the lower parts are covered by the red tint which white marble assumes after long exposure to the weather, and in places with yellow blended with brown. On the top or hog's nose is a hunting scene; some figures are running, others are on horseback galloping, with spears in their hands, and mantles blown by the wind, chasing a stag and a wild boar, which has turned to attack the pursuer. All the figures, though small, are, in the opinion of Sir C. Fellow, well formed and finished. On each of the sloping sides of the roof are two stones projecting about a foot, as found on all these tombs, but which upon this are carved into lions' heads crouching on their paws. Upon one side of the roof is a group, in which a warrior carrying a shield is in the act of stepping into his chariot, which is of the early simple form, with wheels of four spokes only; the driver is leaning forward, with his arms stretched out, holding the reins and a whip or goad; four beautifully formed horses, prancing in various attitudes, are attached to the chariot. It is nearly an old chariot and horses are carved on the other side of the roof, varying only in the attitudes of the figures. In the upper panels at the ends of gables are traces of small carved figures. On one side of the tomb (of which a sketch given in 'Journal' of 1838) under two lines of Lycian characters, is a group of figures, which, beginning from the left, is thus described by Sir C. fellows:—'A finely formed figure in a simple robe, his hands folded before him, and with a head of bushy hair, stands as if in attendance behind the chair or clawed seat of the principal figure, who, clothed in rich folded drapery, with short hair, sits in the attitude of a judge, with one arm somewhat raised; before him stand four figures: the first is mutilated, but appears similar to the second, who has long bushy hair, confined round the head, and looking like a wisp; his attitude is that of a counsellor pleading for the others; the loose robe falls gracefully from his shoulders, and is over, as most to conceal one arm; two other figures, differing only in having the hair shorter and the arms hanging down, stand apparently waiting the decision of the judge, and complete the well-formed group.' The word or name Palaea is inscribed over the judge. At the end, on a larger scale, are two figures of warriors, clothed with short mantles, and girded at the waist, their lions, above petticoats reaching nearly down to their knees. The back-ground of this bas-relief contains a long butt, from mutilation, illegible inscription: it is copied in the Second Journal. On the opposite end of the tomb are two other figures of the same size: one, clothed in a loose robe, stands in a commanding attitude; the spectator, with an arm raised over the head of a naked figure, also standing. (Second Journal, p. 166; where both ends are engraved.)

On the second side of the tomb, under a single line of inscription, is an animated battle-scene: men on horses are fighting with others on foot; all have helmets, and those on foot have shields; some fight naked, others with a loose shirt or blousc descending below the thighs, and confined by a belt round the waist. The horse of the principal figure is ornamented, and with the rider, has a kind of armour to protect his legs. The groups upon the two sides of the tomb are three feet six inches high by nine feet in length. The height of the whole tomb, including the base, is about twenty feet, or twice the width at the base. When first opened, it was found that the tomb was two feet six inches high, but it has been broken open in all its parts. In style of architecture it is the imitation of a wooden structure. Upon the other or Harpy tomb, a high square pedestal which was near the theatre in Xanthus, was readied to house a bas-relief. (First Journal, p. 232, and Second Journal, p. 170, Vol. 11—4 Y
where they are engraved.) On the four extremities of the north and south sides are four figures of similar design; the head is that of a man, a horse, and the body, which terminate the trunk, has wings and a tail like a pig's; from under the wings comes a bird's claw, clasping the legs of a child, which is carried in the bosom of the figure. The tomb has acquired the name of Phereclus, from the fact that Phereclus, king of Similis, was buried in it. The characteristic features of the figures of the charioteers and the costume of the figures of some pieces are of an early age. The forelock of the horses are tied in a peculiar way, similar to those of some horses in a bas-relief at Princeton and at American mounds, as well as the costumes, are in the Persepolitan sculptures the same as in the Xanthian specimens. The horses have also their interest; some resemble the subjects seen upon such Roman coins as the British Museum possesses; in short, there are some prominent objects in these Lycian sculptures. Many of the Greek inscriptions, already mentioned, appear to be subsequent to the Roman conquest of Asia, and some of them are of the time of the emperors.

None of them are of any service in pointing out the date of the various sculptures. They are translated in an 'Appendix to the Journal of the Second Excursion of Sir C. Fellows,' by Mr. Hermann Wiener. Few of them are however quite perfect. The same work contains an Essay on the Lycian Alphabet and Inscriptions, by Mr. Daniel Sharpe. The sculptures and ruins of Cadyanda, Myra, Limyra, Tlos, and the sculptures of the Piagia and the Acropolis in Lycia, appear to be equally interesting as those of Xanthus.

There are in the British Museum fragments of and casts from some of these marvels, as those of Tlos, Telmessus, and of Xanthus, besides many other drawings and paintings of the original sites of the various ruins and marbles, and of some of them entire models as they were first found by Sir C. Fellows in 1838. There is likewise a panoramic view of Xanthus with all its ruins, taken in 1839, from the Acropolis by Mr. George Scharf, who accompanied Sir C. Fellows on his expedition: there are also drawings of the operations of the excavators. In this panoramic view is a group of fragments of Xanthus, introduced; these fragments are now in the Museum, and as they appear all to belong to the same monument, and few pieces are wanting to complete it, a restoration of the whole has been attempted, and it will form one of the most striking features of the collection. It consists of a small amphiprotyle temple of the Ionic order, on a lofty stylobate pedestal without a base, but above a plain lower basement. It measured in height nearly 30 feet above the basement, and as much in length. The stylobate, being rather more than half the height of the whole, is ornamented with the bas-reliefs, and has a cornice with a deep egg-and-tongue moulding. The height of the columns, of which there are four at each end, is ten feet; and between and on the outer sides of these columns are altogether ten figures, five at each end, upwards of five feet in height, but much mutilated.

The pediments were ornamented with sculpture, and three small figures were found on the scotoma, and these figures were found from the Acropolis many beautifully wrought marbles are built in as materials, without any regard to their sculpture. Lions, warriors, chariots, and horses are to be traced in many fragments, and birds like our game-cocks fighting. On the site of a small temple Sir C. Fellows found a frieze about ten or twelve feet long and one in width, representing a series of fifteen small dancing figures with harps. There were the ruins of many small temples in the neighbourhood: Sir C. Fellows considered the sculptures to be Greek. He says however of the ruins generally—"Xanthus possesses some of the earliest archaic sculpture in Asia Minor, and this connected with the most beautiful of its monuments, and illustrated by the language of Lycia. These sculptures to which I refer must be the work of the sixth or seventh century before the Christian era. Many of these fragments have not been despoiled for the rebuilding of walls; and yet the decidedly more modern works of a later people are used as materials in repairing the walls around the back of the city and upon the mound. Many of these drawings, with names common among the Romans. The whole of the sculpture is Greek, fine, bold, and simple, bespeaking an early age of that people. No sign whatever is seen of the works of the Byzantines."

Many Greek inscriptions upon pedestals are built into the walls, which, says Sir C. Fellows, are mostly funeral, and belong to an age and people quite distinct from those of the many Lycian remains. Among the many inscriptions copied by Sir C. Fellows at Xanthus, there is a chaufette for 250 lines taken from an obelisk. (Second Journal, p. 168.) Many of these fragments of sculpture built into the walls of the scarpola are now in the Museum; they are also engraved upon the Temple of Selene and the Temple of the Dioscuri. The statuary of the charioteers and the costume of the figures of some pieces are of an early age. The forelock of the horses are tied in a peculiar way, similar to those of some horses in a bas-relief at Princeton and at American mounds, as well as the costumes, are in the Persepolitan sculptures the same as in the Xanthian specimens. The horses have also their interest; some resemble the subjects seen upon such Roman coins as the British Museum possesses; in short, there are some prominent objects in these Lycian sculptures. Many of the Greek inscriptions, already mentioned, appear to be subsequent to the Roman conquest of Asia, and some of them are of the time of the emperors.
one of the pediments also shows that the Persian is the defeated, not the victorious party. That monument is a creation of the Persians, not of the partings.

If this monument can be explained into a monument to Harpagus, it must have been executed about 150 years after the event commemorated; for though it may be hazardous to fix the time of construction of the monuments erected in the wake of a victorious army, there is no real risk in pronouncing when it was not executed; and there is evidence in the design and workmanship in this monument to show that it was not executed under the Persians. In fact, he is not represented as the Persian, or certainly not earlier than about 400 B.C., and probably considerably later. After a certain time, when mastery has superseded hesitation in design and unskilfulness of execution, the straight lines of the cramped stiffness of attitude are replaced by freedom and facility, with everywhere the evidence of a skilful expression of what was required. The journeys also by whom such marbles are executed, long accustomed to the easy mastery of the models of a finished age, themselves acquire peculiar characteristics of execution; a touch given with little trouble, by which much is accomplished; grown old in mastery, they become careless and free to extravagance in their execution. All these evidences are in this Xanthian monument: the draperies of the mutilated female statues combine the highest mastery in design with the utmost facility of execution.

Besides the works above quoted on these marbles, Sir C. Fellowes has published a pamphlet entitled 'The Xanthian Marbles,' in 1843, in order that they might be inspected. Their inscriptions are already incorporated in the 'Corpus Inscriptionum Graecarum,' by Aug. Boeckh and J. Franz, in the first part of the third volume of the Transactions of the Academy of Sciences of Berlin for 1844. Some corrections are ventured upon by the editors of this edition, especially in an inscription on a stake or column described as erected to a son of Harpagus, who was a celebrated boxer. (Kenneth, 1845, p. 322.)

XANTHII DIUM.

Some of the minute organic bodies in the chalk and flint of England are referred to this genus of Infusoria, but perhaps without sufficient reason. (Maull.)

XAVIER, FRANCIS, SAINT, was born at the castle of Xavier, in Navarre, on 7th April, 1506. His father, Don John de Jasso, was a counsellor of state to the King of Navarre, and his mother, Maria Azpilcueta, was heiress of the two illustrious houses of Azpilcueta and Xavier. Francis was the youngest of a large family of children, the eldest of whom bore the surname of Azpilcueta, and the others that of Xavier. Under the paternal roof he received all the advantages of their education, and by the talents which he manifested, induced his parents to send him at the age of eighteen to the Collège de Sainte Barbe, at Paris. It was there that he first became acquainted with Ignatius Loyola, and the discipline of his society, and he left it in 1528. Although he continued his studies, the history of Xavier is intimately blended with that of Loyola and his disciples. (Jasuits, P. C.; Loyola, P. C. S.)

Ignatius Loyola at Rome, where he and Francis Xavier first met, was active in the furtherance of his great design of associating a body of devoted men for the special service of the Church of Rome. While in that city, he exercised the functions of the ministry in the church of St. Lawrence in Damaso, and attracted to it large multitudes by his zeal and talents. Among them was a Portuguese of the name of Gove, who had been sent to Rome on a mission of importance by King John III. In his communications with the king he had expressed himself in terms of high commendation of the new society which had lately sprung up under Loyola; and had suggested the propriety of selecting missionaries from among the Jesuits to proclaim the Faith in the Portuguese colonies of Asia. Influenced by these representations, the king dispatched an order to his ambassador at Rome to obtain six members of that society, who might be willing to devote themselves to the work of missions in India. Later, the Jesuits on the island of Abozimas, where he baptized a large number of the inhabitants; he then preached the Gospel in other islands, and, having made a considerable stay in the island of Malacca, he returned to the European ports, and put to sea on his voyage to the island of Ceylon, where he converted the King of Ceylon and several of his subjects; on the 20th May, 1548, he returned to Goa. At Malacca, he had met with a Japanese of the name of Auger, named Augustus, an islander of the name of Abozimas, having been instructed in the faith, and induced to accompany him to Goa. The description given by this Japanese of the state of his native islands determined Xavier to go among them on making them acquainted with the true religion. Having baptized Auger, with two of his domestic, and given
him the more Christian name of Paul of the Holy Faith, he set out within four days at Grenville, and arrived at Macassar on the 15th August, 1549, at Canggorima, in the kingdom of Sambara, in Japan. [JAPAN, P.C.]

The chief difficulty he had to overcome in this new mission was his ignorance of the Japanese language. Xavier, urging his voyage, had, by means of his convert, acquired me little knowledge of it, which was increased by his stay of forty days at Canggorima, and which was sufficient to enable him to translate into it the Apostles’ creed with a short exposition. The little progress, however, which he made in it proved a serious hindrance to his success, as appears from the letters he sent home. Through his conversion, he was introduced to the King of Sambara, who gave him a favourable reception, but declined hearing him on the subject of religion. In the hope of finding a more suitable field for his missionary exertions, he left Sambara, and proceeded to Frando, the capital of another small kingdom. He was there allowed freely to exercise his ministry, and numerous conversions were the fruits of it: In that city he baptized more infidels, in twenty days, than he had done at Canggorima in a whole year. Encouraged by this success, he left those converts under the care of one of the Jesuits who had accompanied him, and set out for Meaco, the capital of the whole empire of that archipelago where he had an audience of Emperor, and all his court. [JAPAN, P.C.] On his way thither he visited Amanguchi, the principal town of the kingdom of Nagato, where he was allowed to pass the night before the king and his court, but his little success. After a month’s stay in that city, he continued his journey towards Meaco. Though it was the depth of winter, and the rugged roads, difficult at all times, were now rendered almost impassable by drifts of snow and mountain torrents, yet, thinly clad and barefoot, he journeyed onwards, resigned and cheerful. He arrived at Meaco in February, 1551, having been about two months on his journey. There his mean appearance and worn garments proved a subject of offence to the inhabitants; accustomed to the gorgeous rites and pompous ceremonies of their own religion, the priests, whose influence was paramount in that city, could not see in this humble Jesuit the ambassador of God. High though rejected with contumely, Xavier did not abandon his holy purpose, but returned to Amanguchi, where he provided himself with a rich mitre and a retinue of attendants, and thus attired presented himself before the court. This harmless device produced the desired effect; he obtained the protection of the king, and preached with so much success, that he baptized three thousand persons in that city. Those converts he left to the care of some Jesuits who had been the companions of his journey; and, accompanied by two Japanese Christians, who, rather than renounce the consolations of the religion he had taught them, had cheerfully suffered the confiscation of their property, were departed from Amanguchi, in September, 1551, and, on the 20th of November following, embarked to return to India, having remained in Japan two years and four months. The voyage was, for upwards of a hundred years after the death of Xavier, successfully continued by the Jesuits. [MISSIONS, P.C., vol. xv, p. 267.]

On his voyage he made some stay at Malacca, chiefly for the purpose of concerning measures with the government of that place for the prosecution of a mission to China. A serious obstacle to it was the law which forbids strangers, on the severest penalties, to enter that country. To remove it, it was agreed between Xavier and the governor of Malacca that an envoy should be sent to the name of the King of Portugal to establish a commercial treaty, and that Xavier should join it. On his return, however, to Malacca, he found the new governor, who had arrived there during his absence, opposed to the projected embassy, and, after many unsatisfactory entreaties to procure his compliance, he was obliged to embark alone for his intended mission on board a Portuguese vessel bound for the island of Sancian, near Macao, in China, a place where the Chinese were permitted to traffic with the Portuguese merchants. On arriving there, the merchants of Sancian endeavoured to dissuade him from his design of proceeding into China, but strongly persisted in the matter. Xavier however was not to be deterred; he provided himself with an interpreter, and entered into an agreement with a Chinese merchant to land him by night on some part of the coast. This plan also was frustrated by the Portuguese residents of Sancian, who feared that this attempt to infringe the laws might be visited upon them by the vengeance of the Chinese authorities. While thus disappointed in his first hopes, he fell severely sick. His sufferings, which were most acute, were aggravated by the inattention and want of skill of those around him; in the midst of them however he displayed a cheerful countenance and a holy resignation. He died on the 29th of December, 1552. His remains were brought over to Malacca on the 22nd of March, 1553, where they were received with the greatest honour; they were afterwards transferred to Goa, and deposited in the principal chapel of the church of Paul, on the 16th of March, 1567. The memory of Francis Xavier was consecrated by a ceremony known in the church of Rome by the name of Beatification, by the Pope Paul V., in 1609, and he was canonized as a Saint by Gregory XV. in 1623. In 1647, John IV. of Portugal, obtained a brief of Benedict XIV., which conferred on him the title of patron and protector of the East Indies. His feast is observed by the Church of Rome on 3rd of December.

This biography there is an error in the date both of his beatification and canonization; Biographie Universelle, tome ii.; and another states, in this work is by Lopéz; Fabre, Connaissance de l’Histoire Ecclésiastique de France, livres xxxiv., xxxix., cxxii., cxxviii., Lettres délibérantes et curieuses, écrites par des Missionsnaires de la Compagnie de Jésus, 40 vols. Paris, 1832, vol. xxvii., a work of great curiosity and interest, and not sufficiently known in England; P. Cyclo. art. ‘Missions’; the statement made in it that Xavier was canonized by Urban VIII. is erroneous, but it is true that this Pope gave him the title of the Apostle of the Indies. The Life of St. Francis Xavier has also been written in Latin, by Tursellini, Rome, 1604; in Italian, by Orlandino, Bartoli, and Maffei; and in French, by Bouchoux, a work which was translated into English by Dryden in 1686.

XULONIOSPRONITIES, one of the fossil fruits of Sheppey. (Bowerbank.)

XYLOPIA, a genus of plants belonging to the natural order Annonaceae. It has 6 petals and numerous stamens; the calyx from 3- to 5-lobed, the segments ovate, connate, and acute; the ovaries distinct and numerous; the ovules ascending in one row attached to the central axis; the fruit globular, dry, compressed, indehiscent, and stalked, and from 1- to 4-seeded.

X. longifolia is a tree 70 feet high, the leaves oblong, acuminate, silky, and shining beneath, revolute at the margin; the flowers sessile, axillary and smooth; the three outer petals oblong, linear, acuminate, silky, brownish, externally white, and excavated in the inside; the three inner ones linear, white, red at the base, 3-corrugated at the point.

X. glabra is a tree native of Jamaica and Barbadoes. The branches are smooth and scarcely dotted; the leaves oblong, ovate, smooth on both sides, obtuse at the base, acuminate at the apex, 1-flowered, solitary or in pairs. The calyx is smooth, trifid, with very stout lobes; the carpels smooth. The flower-buds are oblong, pubescent on the outside. The wood, bark, and heart of this tree are an agreeable bitter taste, similar to that of an orange-seed.

All the species of this genus require a stove-heat. They grow best in sandy loam and peat, and ripened cuttings will root in sand under a bell-glass in moderate heat.

(From, Gardner's Dictionary; Lindley, Flora Medica.)

Z.

ZAMITEES, a genus of fossil Cycadeoidea from the colitic, wealden, and cretaceous formations (Pres.) synonymously with Mantellia and Brongniart. It is found in South Africa, at the western extremity of the Gulf of Aden, not far from the Straits of Bab-el-mandeb. It is situated in 17° 45' N. lat. and 43° E. long. The harbour is small and shallow, so that even small vessels can not enter it. It is only three miles from the town to the beach. The town is enclosed by walls now in ruins. The houses, with the exception of eight or ten, which are built of stone, are either of wood or reeds, or of both these materials. Some guns planted on the wall from the land side are sufficient protection against the Somalis, who inhabit the surrounding country. The population is not to exceed five hundred souls. All families are engaged in trade. Zella being one of the harbours by which the inhabitants of Hurras carry on a commercial intercourse with Arabia. Three caisles arrive annually from the interior, especially from Hurras. They bring to Zeila slaves, both male and female, large quantities of gum and myrrh, coffee, jowari, ghee, and ostrich feathers, also some grain, especially millet, wheat, and beans. Most of these articles are sent to Mocha, and at present probably also to Aden. In return they take back blue and white coarse cloth, Indian piece goods, European prints, silk, silk thread, shawls, red cotton yarn called shumlah, beads, zinc, copper-wire, frankincense, and Australian dollars. Zeila is subject to the Pasha of Egypt, by whose authority the Doleh of Moha nominates the Emir Zeila, who pays an annual tribute of 300 dollars, and keeps a garrison of seventy soldiers, armed in part with matchlocks.

ZAIM, SHAH. [SHAM ZAIM, P. C.]

ZINC, Medical Properties of.—In the purely metallic state, zinc produces no effect on the human system, but its combination with oxygen is sufficient to invest it with considerable power over the organs, both those with which it comes into direct contact and some remote ones, especially the nervous centres. Its local action is that of an irritant, astringent, and desiccative, while its remote action is that of a purgative. The acid acts upon the stomach, its properties are less than those of the sulphate or acetate, unless it meets with acids in the stomach. In this way it is rarely employed. It is for its remote effects, when taken in small long-continued doses, that it is valuable. While it has the properties common to all the metallic antispasmodics, it is distinguished by its power of restraining inordinate action of the nervous system; being calming and soothing. The brain and the function of sensation appear to feel less of its influence than the spinal chord. Hence the nerves of motion, and the functions of the circulation and respiration, are chiefly acted upon; it produces its effects speedily, but they quickly disappear when given in such doses as can be safely administered. The long continued use of it seems to produce a dryness and induration of the frame, which if carried to excess is dangerous, but the lesser degree of which is in all probability the source of the utility of this medicine, by diminishing the mobility of the irregularities in the circulation, and sudden congestions of blood, being the immediate causes of attacks of epilepsy and hysteria, the diseases which are most benefited by zinc.

In spasmodic affections of the chest, such as asthma, angina pectoris, and palpitation of the chest, when these do not proceed from organic derangements, oxide of zinc is often serviceable. In its use, the cramps of the stomach to which habitual drunkards are subject, is very useful.

Pure oxide of zinc is called tarry. It is sometimes used externally as a dusting powder, as a mild absorbent, on excoriations, and to heal chaps and cracks in the skin. It is also used as an ointment. Pure oxide of zinc forms an ointment of much value where an astrigent is needed, especially in the chronic inflammation of the skin.

Carbonate of zinc when impure is termed calamine; this after being subjected to diverse processes, is called prepared calamine. The only use made of it is to form an ointment, which is most useful as an application to burns, excoriations, and superficial ulcers.

Sulphate of zinc is in small doses a very valuable astringent, tonic, and antispasmodic; in larger doses it is a very certain and speedily acting emetic; and in very large doses it is poisonous. It is the sulpha of this element which excited the medical profession, as it is not so apt to inflame the stomach as tartrated antimony: but the stomach-pump is preferable to either. The tonic effects are best seen in affections of the mucous membranes. In the sanguineous catarrh of aged persons, and the extreme defluxions on the chest after influenza, sulphate of zinc affords a valuable remedy: it must be given in small doses, as the sudden suppression of the secretion may cause inflammation. The use of the solution as an injection requires the same caution.

Acetate of zinc is possessed of nearly similar properties, but in a weaker degree; and as an injection, seems in some cases entitled to a preference.

Chloride of zinc, called also butter of zinc, is a powerful escharotic or caustic; this action results from its strong affinity for albumen and gelatine, which principles it abstracts from the living tissues, and so forms an eschar. Its powers in this way have been taken advantage of to destroy parts affected with malignant diseases, such as cancer and lupus, and to remove newt matrial, or mother-marks. In none of these is it to be resorted to unless they are very superficial. Deep-seated cancer of glands can scarcely be removed by it, but other forms are often successfully treated by it. (Walh eOn Cancer, p. 219.)

Cyanide or cyanuret of zinc is a powerful antispasmodic and tonic. No medicine is so potent in allaying irritation of the stomach attended with great debility. The dose must be small and often repeated. Valerianate of zinc has lately been much recommended as a remedy against tic-douloureus and other nervous affections. Where the patients can tolerate the repulsive odour and puerescence in its use, it often proves very serviceable.

Zinc pans have been much recommended for use in dairies, as the milk specifically coagulates in them, and the quantity of cream is great; but if the milk become sour while in them, the acid acts upon the milk, and the white particles are perhaps not poisonous compounds. Upon the whole, white porcelain vessels, kept thoroughly clean, are the best material for milk-receivers.

ZINGIBER OFFICINALE:—(GINGER, Medical Properties of. The native country of this plant seems unknown, though Goebel asserts that it is Guinea. It is however extensively cultivated in China, Java, and the East and West Indies. From the composition of the zinc it is procured. Of this there are two varieties, the black and white; but some writers affirm that these are the produce of two distinct species, while others ascribe the difference to appearance to diversity of treatment after the rhizome is dug up. The rhizome or root-stock is perennial, but it is only that of a young plant, or the annual shoots from an old one, which are met with in commerce. When first dug up, the colour internally is red. The principal year's first year are used fresh, or preserved in sugar, and constitute the sweetmost as preserved ginger. This, when sent from the West Indies, is in small, round, tender pieces; when from the East, larger, flat, and stringy portions: the former is preferred.

Black ginger is stated to be the rhizome dug up, scaled in hot water, and dried in the sun. White ginger is also marketed, and then wrapped to free it from the soil before it is dried, which last operation is said to be effected by artificial heat, but probably mostly by the sun. Both kinds are very liable to the attacks of an insect: to prevent these attacks the rhizomes are dipped in a solution of lime, which destroys the insect of which often adheres to the surface. To cause black ginger to resemble the white it is bleached, after its arrival in this country, in a solution of chloride of lime, or exposed to the fumes of burning sulphur. This impairs the activity of the article.
Ginger occurs in commerce in pieces termed races, of various shapes, but generally flatish, branched, lobed, or palmated, rarely more than four inches long. The unscraped has a wrinkled epidermis; the scraped is devoid of this covering. Jamaica ginger, which is most esteemed in this country, occurs in races larger, rounder, and thinner than the other kinds; externally of a yellowish white, internally of a yellowish hue. The taste is agreeably aromatic and pungent, but this is lost with age, so that old pieces are worthless, as are also portions which have been digested in alcohol to form essence of ginger. Ginger when chewed excites a flow of saliva; the powder applied to the nostrils causes sneezing. The quantitative analysis of 100 parts of ginger has been given by Bucholz:—

Morin's analysis yields also acetic acid, acetate of potash, and sulphur; while the ashes give numerous metallic salts and alkaline salts.

The volatile oil is of a pale yellow, lighter than water; taste at first mild, then hot. The soft resin, obtained by digesting the alcoholic extract of ginger first in water, then in ether, and evaporating the ethereal tincture, is not quite ana-

logous to the principle zingiberin, procured by Beral, and by him termed peperaud. This last is got by submitting ginger directly to the action of sulphuric ether. Beral recommends many preparations of this principle, but, except from their smaller bulk, it is difficult to perceive what advantage they possess over common ginger and its preparations. Ginger is an aromatic stimulant of considerable power. The effects are greater on organs with which it comes into direct contact than on remoter ones. Thus, when chewed, it is a powerful stylogue, and relieves tooth-ache, rheumatism of the jaw, and also relaxed uvula. When received into the stomach, it promotes digestion in languid habits, and relieves flatulent colic. Gouty subjects are much benefited by it, and for such persons no form is more beneficial than that of preserved ginger taken at dessert after a mixture of viands. But it has the disadvantage of impairing the flavour of the wine taken at the same time.

The action of ginger on remote organs is greatest on the mucous membranes. Hence the lungs are markedly excited in the relaxed and suffocative catarrah of old people. The mucous membranes of the urino-genital organs are also excited by it in languid habits; many feeble females receive much advantage from the domestic preparation termed ginger-tea. Some headaches of a sympathetic kind, originating in irritation of the intestinal canal, are often relieved by it. A poultice of scraped ginger, to which warm water has been added, forms a substitute for a mustard poultice, and often relieves headache when applied to the forehead. Ginger-beer is often a grateful beverage in summer heat, but with some persons it disagrees; this is owing to the sugar; for if made without it, it agrees with such persons well. Lemon-juice, when taken with sugar, often disagrees, as for example with pancakes. The lemon-juice alone is most wholesome.
